Introduction	13
What's new from version 3.0 ?	14
Content	15
Unitex contributors	16
If you use Unitex in research projects...	17
1 Installation of Unitex	19
1.1 Licenses	19
1.2 Java runtime environment	20
1.3 Installers	20
1.3.1 Installer for Windows	20
1.3.2 Installer for GNU/Linux and OS X	21
1.4 Manual installation	23
1.5 First use	23
1.6 Adding new languages	24
1.7 Uninstalling Unitex	25
1.8 Unitex for developers	25
2 Loading a text	27
2.1 Selecting a language	27
2.2 Text formats	27
2.3 Editing text files	30
2.4 Opening a text	30
2.5 Preprocessing a text	31
2.5.1 Normalization of separators	33
2.5.2 Splitting into sentences	33
2.5.3 Normalization of non-ambiguous forms	35
2.5.4 Splitting a text into tokens	36
2.5.5 Applying dictionaries	38
2.5.6 Analysis of compound words in Dutch, German, Norwegian and Russian	41
2.6 Opening a tagged text	42

3	Dictionaries	43
3.1	The DELA dictionaries	43
3.1.1	The DELAF format	43
3.1.2	The DELAS Format	46
3.1.3	Dictionary Contents	47
3.2	Looking up a word in a dictionary	49
3.3	Checking dictionary format	50
3.4	Sorting	51
3.5	Automatic inflection	53
3.5.1	Inflection of simple words	53
3.5.2	Advanced inflection operators	57
3.5.3	Inflection of compound words	61
3.5.4	Inflection of Semitic languages	61
3.6	Transliterating Arabic dictionaries	63
3.7	Compression	64
3.8	Applying dictionaries	68
3.8.1	Priorities	68
3.8.2	Application rules for dictionaries	69
3.8.3	Dictionary graphs	69
3.8.4	Morphological dictionary-graphs	73
3.9	Bibliography	74
4	Searching with regular expressions	75
4.1	Definition	75
4.2	Tokens	75
4.3	Lexical masks	76
4.3.1	Special symbols	76
4.3.2	References to information in the dictionaries	77
4.3.3	Grammatical and semantic constraints	77
4.3.4	Inflectional constraints	78
4.3.5	Negation of a lexical mask	79
4.4	Concatenation	80
4.5	Union	81
4.6	Kleene star	82
4.7	Morphological filters	82
4.8	Search	84
4.8.1	Search configuration	84
4.8.2	Presentation of the results	85
4.8.3	Statistics	90
5	Local grammars	93
5.1	The local grammar formalism	93
5.1.1	Algebraic grammars	93
5.1.2	Extended algebraic grammars	94
5.2	Editing graphs	94

5.2.1	Creating a graph	94
5.2.2	Sub-Graphs	99
5.2.3	Manipulating boxes	102
5.2.4	Transducers	103
5.2.5	Input Variables	105
5.2.6	Copying lists	106
5.2.7	Special Symbols	107
5.2.8	Toolbar Commands	108
5.3	Display options	110
5.3.1	Sorting the lines of a box	110
5.3.2	Zoom	111
5.3.3	Antialiasing	112
5.3.4	Box alignment	113
5.3.5	Display options, fonts and colors	114
5.4	Exporting graphs	116
5.4.1	Inserting a graph into a document	116
5.4.2	Printing a Graph	118
6	Advanced use of graphs	119
6.1	Types of graphs	119
6.1.1	Inflection transducers	119
6.1.2	Preprocessing graphs	120
6.1.3	Graphs for normalizing the text automaton	121
6.1.4	Syntactic graphs	122
6.1.5	ELAG grammars	122
6.1.6	Parameterized graphs	123
6.2	Compilation of a grammar	123
6.2.1	Compilation of a graph	123
6.2.2	Approximation with a finite state transducer	123
6.2.3	Constraints on grammars	124
6.2.4	Interval for number of repetitions	127
6.2.5	Error detection	128
6.3	Contexts	128
6.3.1	Right contexts	128
6.3.2	Left contexts	131

Introduction

Unitex is a collection of programs developed for the analysis of texts in natural language by using linguistic resources and tools. These resources consist of electronic dictionaries, grammars and lexicon-grammar tables, initially developed for French by Maurice Gross and his students at the Laboratoire d'Automatique Documentaire et Linguistique (LADL). Similar resources have been developed for other languages in the context of the RELEX laboratory network.

The electronic dictionaries specify the simple and compound words of a language together with their lemmas and a set of grammatical (semantic and inflectional) codes. The availability of these dictionaries is a major advantage compared to the usual utilities for pattern searching as the information they contain can be used for searching and matching, thus describing large classes of words using very simple patterns. The dictionaries are presented in the DELA formalism and were constructed by teams of linguists for several languages (French, English, Greek, Italian, Spanish, German, Thai, Korean, Polish, Norwegian, Portuguese, etc.)

The grammars used here are representations of linguistic phenomena on the basis of recursive transition networks (RTN), a formalism closely related to finite state automata. Numerous studies have shown the adequacy of automata for linguistic problems at all descriptive levels from morphology and syntax to phonetic issues. Grammars created with Unitex carry this approach further by using a formalism even more powerful than automata. These grammars are represented as graphs that the user can easily create and update.

Lexicon-grammar tables are matrices describing properties of some words. Many such tables have been constructed for all simple verbs in French as a way of describing their relevant syntactic properties. Experience has shown that every word has a quasi-unique behavior, and these tables are a way to present the grammar of every element in the lexicon, hence the name lexicon-grammar for this linguistic theory. Unitex offers a way to automatically build grammars from lexicon-grammar tables.

Unitex can be viewed as a tool in which one can put linguistic resources and use them. Its technical characteristics are its portability, modularity, the possibility of dealing with languages that use special writing systems (e.g. many Asian languages), and its openness, thanks to its open source distribution. Its linguistic characteristics are the ones that have motivated the elaboration of these resources: precision, completeness, and the taking into

account of frozen expressions, most notably those which concern the enumeration of compound words.

What's new from version 3.0 ?

Here are the main new features:

- Faster engine that uses less stack.
- Enhanced version of CasSys: new `csc` files, suppression of the `Share` directory, open cascade also by the `FSGraph` menu, apply graph until fixed point, generic graphs, last file may be denormalized (Chapter 12).
- Introduction of Malagasy.
- Publication of `main_UnitexTool_C` as public API.
- Enhanced version of the graph editor: box selection, box editing, open, save, export as image (5.2, 5.4).
- Non-applicable menu items are now grayed out.
- Introduction of the `<n . LEMMA>` operator for inflection in Semitic mode (yet undocumented).
- Introduction of list of recently opened graphs and corpora.
- Introduction of list of open windows.
- Enhanced compatibility with Ruby.
- Introduction of `InstallLingResourcePackage`, a tool that installs a package of resources and scripts into a target environment (yet undocumented).
- Introduction of `RunScript`, a tool that runs in the target environment scripts installed there by `InstallLingResourcePackage` (yet undocumented). With these two tools, users can implement Unitex operations in an environment and deploy them in another.
- Introduction of the "match word boundaries" option in the automaton-intersection search algorithm (7.7), so that e.g. *nowhere* and *now here* don't match (or match, if user wants). Yet undocumented.
- Enhanced tracking of the offset between the addresses of a given position in a corpus in different versions of the corpus (13.13).
- Daily compilation of binaries for Windows (32-bit, 64-bit), GNU/Linux (Intel, Intel 64-bit) and OS X (10.7+).
- Setup installers are provided for all target platforms.

IMPORTANT: as some file formats changed and some new files were introduced, we recommend that you reprocess your existing text files, especially if you work with text automata.

Content

Chapter 1 describes how to install and run Unitex.

Chapter 2 presents the different steps in the analysis of a text.

Chapter 3 describes the formalism of the DELA electronic dictionaries and the different operations that can be applied to them.

Chapters 4 and 5 present different means for making text searches more effective. Chapter 5 describes in detail how to use the graph editor.

Chapter 6 is concerned with the different possible applications of grammars. The particularities of each type of grammar are presented.

Chapter 7 introduces the concept of text automaton and describes the properties of this notion. This chapter also describes operations on this object, in particular, how to disambiguate lexical items with the ELAG program.

Chapter 8 describes the sequence automaton module, the file formats that are accepted as input, the user interface and introduces the search by approximation.

Chapter 9 contains an introduction to lexicon-grammar tables, followed by a description of the method of constructing grammars based on these tables.

Chapter 10 describes the text alignment module, based on the XAlign tool.

Chapter 11 describes the compound word inflection module, as a complement of the simple word inflection mechanism presented in chapter 3.

Chapter 12 describes the CasSys cascade of transducer system.

Chapter 13 contains a detailed description of the external programs that make up the Unitex system.

Chapter 14 contains descriptions of all file formats used in the system.

The reader will find in appendix the LGPL license under which the Unitex source code is released, as well as the LGPLLR license which applies for the linguistic data distributed with Unitex. There is also the 2-clause BSD licence that applies to the TRE library, used by Unitex for morphological filters.

Unitex contributors

Unitex was born as a bet on the power of Open Source philosophy in the academic world (see http://igm.univ-mlv.fr/~unitex/why_unitex.html), relying on the assumption that people would be interested in sharing their knowledge and skill into such an open project. The following list sounds like Open Source is good for science:

- Olivier Blanc: has integrated the ELAG system into Unitex, originally designed by Eric Laporte, Anne Monceaux and some of their students, has also written `RebuildTfst` (previously known as `MergeTextAutomaton`)
- Matthieu Constant: author of `Grf2Fst2`
- Julien Decreton: author of the text editor integrated in Unitex, has also designed the undo functionality in the graph editor
- Claude Devis: introduction of morphological filters, based on the TRE library
- Nathalie Friburger: author of `CasSys`
- Hyun-Gue Huh: author of the tools used to generate Korean dictionaries
- Claude Martineau: had worked on the simple word inflection part of `MultiFlex`
- Sebastian Nagel: has optimized many parts of the code, has also adapted `PolyLex` for German and Russian
- Alexis Neme: has optimized `Dico` and `Tokenize`, has also merged `Locate` into `Dico` in order to allow dictionary graphs
- Aljosa Obuljen: author of `Stats`
- Sébastien Paumier: main developer
- Agata Savary: author of `MultiFlex`
- Anthony Sigogne: author of `Tagger` and `TrainingTagger`
- Gilles Vollant: author of `UnitexTool`, has optimized many aspects of Unitex code (memory, speed, multi-compiler compliance, etc)
- Patrick Watrin: author of `XMLizer`, has worked on the integration of `XAlign`

Moreover, Unitex would be useless without all the precious linguistic resources it contains. All those resources are the result of hard work done by people that shall not be forgotten. Some are mentioned in disclaimers that come with dictionaries, and complete information is available on:

http://igm.univ-mlv.fr/~unitex/linguistic_data_bib.html

If you use Unitex in research projects...

Unitex has been used in several research projects. Some are listed in the “Related works” section of Unitex home page. If you did some work with Unitex (resources, project, paper, thesis, ...) and if you want it to be referenced in the web site, just send a mail to unitex-devel@univ-mlv.fr. The more visible, the more cited!

Chapter 1

Installation of Unitex

Unitex is a multi-platform system that runs on Windows as well as on Linux or OS X. This chapter describes how to install and how to launch Unitex on any of these systems. It also presents the procedures used to add new languages and to uninstall Unitex.

1.1 Licenses

Unitex is free software. This means that the source of the programs is distributed with the software, and that anyone can modify and redistribute it. The code of the Unitex programs is under the LGPL licence ([36]), except for:

1. the TRE library for dealing with regular expressions by Ville Laurikari ([65]), which is under a 2-clause BSD-style license;
2. the wingetopt library, by Todd Miller and the NetBSD Foundation, also under a 2-clause BSD-style license, more permissive than the LGPL;
3. the pstdin library, a cross platform source code header for precisely sized integers on all platforms, by Paul Hsieh, which is under a 3-clause BSD-style license;
4. the Xerces2-j XML Parser, by the Apache Software Foundation, which is under the Apache Software License version 2.0;
5. the LibYAML library by Kirill Simonov, under MIT license, which is also more permissive than LGPL;
6. the SVNKit library by TMate Software, which is under TMate license.

The LGPL license is more permissive than the GPL, because it makes it possible to use LGPL code in nonfree software. In both cases, the software can be freely used and distributed.

All the language resources that go with Unitex are distributed under the LGPL license ([54]).

Full text versions of LGPL, 2-clause BSD, Apache, MIT, TMate and LGPL license can be found in the appendices of this manual.

1.2 Java runtime environment

Unitex consists of a graphical interface written in Java and external programs written in C/C++. This mixture of programming languages is responsible for a fast and portable application that runs on different operating systems.

Before you can use the graphical interface, you first have to install the runtime environment, usually called Java virtual machine or JRE (Java Runtime Environment).

For the graphical mode, Unitex needs Java version 1.6 (or newer). If you have an older version of Java, Unitex will stop after you have chosen the working language.

You can download the virtual machine for your operating system for free from the Sun Microsystems web site ([70]) at the following address: <http://java.sun.com>.

If you are working under Linux or OS X, or if you are using a Windows version with personal user accounts, you have to ask your system administrator to install Java.

1.3 Installers

The Unitex/GramLab installers can be downloaded from:

<http://releases.unitexgramlab.org/latest-rc>

1.3.1 Installer for Windows

The downloaded file will be named something like:

```
Unitex-GramLab-3.1rc_win32-setup.exe  
Unitex-GramLab-3.1rc_win64-setup.exe
```

Then, double-click on this file and follow the instructions (Fig. 1.1). It is recommended to uninstall any existing versions before installing a new one. Unitex/GramLab will be installed in a directory (folder) which should preferably be located in the `Program Files` directory, and which will be called in this manual the Unitex system directory.

When the installation is finished, a Unitex icon and a GramLab icon should appear on the desktop: double-click on them to start Unitex or GramLab (see 1.5). (If the installer did not create these icons, open the Unitex system directory: it contains several subdirectories, one of which is named `App`. This directory contains two files named `Unitex.jar` and `GramLab.jar`. They are the Java files that launch the graphical interfaces. Double-click on one of them to start Unitex or GramLab (see 1.5). To facilitate launching the interface, you may want to add shortcuts to these files on the desktop.)

If Unitex is to be installed on a multi-user Windows machine, it is recommended that the system administrator performs the installation. If you are the only user on your machine, you can perform the installation yourself.

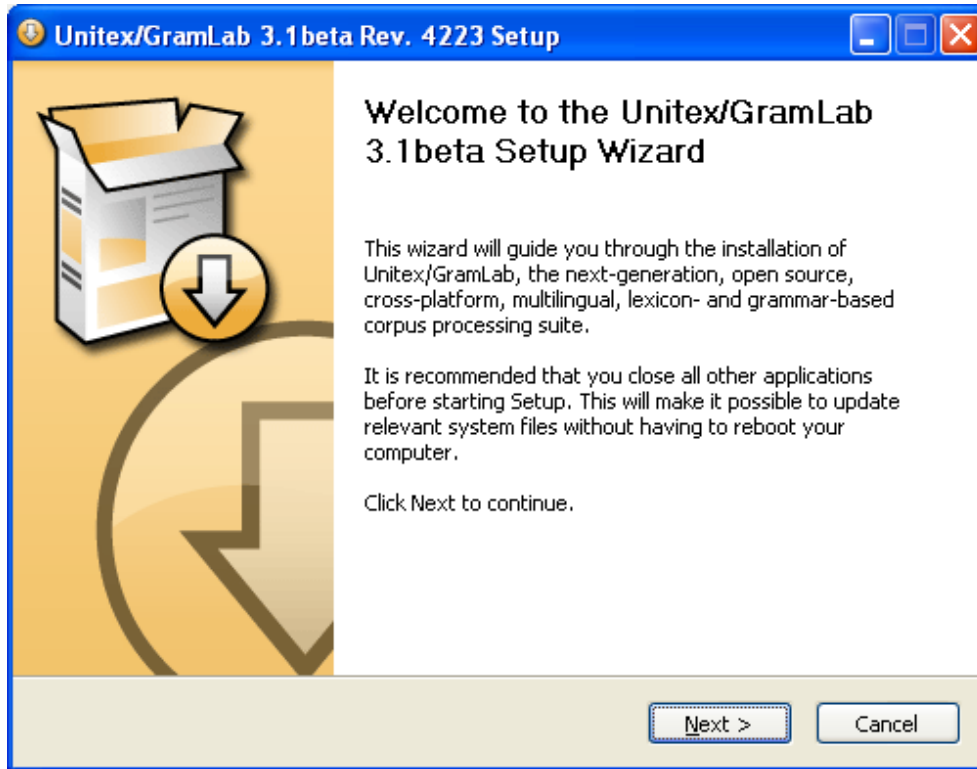

Figure 1.1: The Windows installer

The Windows installer can also be launched in command line and accepts several optional command line parameters. Some of them are:

<code>/AllUsers</code>	Sets default to a per-machine install
<code>/CurrentUser</code>	Sets default to a per-user install
<code>/D C:\path\without quotes\</code>	Sets the default installation directory
<code>/NCRC</code>	Skip the cyclic redundancy check
<code>/S</code>	Runs the installer silently

If you run Unitex under Windows 7, you may experience trouble with your Unitex configuration file, because Unitex tries to write it in the `Users` subdirectory, and Windows 7 forbids it.

1.3.2 Installer for GNU/Linux and OS X

The downloaded file will be named something like:

```
Unitex-GramLab-3.1rc-linux-i686.run
Unitex-GramLab-3.1rc-linux-x86_64.run
```

Then, give it executable permissions, by typing, for example (Fig. 1.2):

```
chmod a+x Unitex-GramLab-3.1rc-linux-i686.run
```

The `.run` file is a self-extracting archive. Execute it with:

```
./Unitex-GramLab-3.1rc-linux-i686.run
```

```

Unitex/GramLab 3.1beta Rev. 4234
December 17, 2015

Unitex/GramLab is an open source, cross-platform, multilingual,
lexicon- and grammar-based corpus processing suite. Project home page
can be found from: http://unitexgramlab.org.

To use this software you need to accept the terms and conditions of the
following licenses:

* All Unitex/GramLab programs, libraries and source codes are
distributed under the terms of the GNU Lesser General Public License
version 2.1 (LGPLv2), which itself incorporates the terms and
conditions of the GNU General Public License. You can get a copy of the
license at http://opensource.org/licenses/lgpl-2.1

* Linguistic Resources are distributed under the terms of the Lesser
General Public License For Linguistic Resources (LGPLLR). You can get a
copy of the license at https://spdx.org/licenses/LGPLLR

* Documentation is licensed under the terms of the GNU Free
Documentation License version 1.3 (GFDL), as published by the Free
Software Foundation. You can get a copy of the license at
http://www.gnu.org/licenses/fdl-1.3.txt

* Unitex/GramLab includes copyrighted third-party libraries licensed
under the terms of the Apache Software License version 2.0
(Apache-2.0), the BSD 2-Clause License (BSD License), and the MIT
License (MIT). All third-party packages are copyright by their
respective authors.

```

Figure 1.2: The GNU/Linux and OS X installer

The GNU/Linux and OS X installer accepts several optional command line parameters. Some of them are:

<code>--confirm</code>	Ask before running the embedded installation script
<code>--quiet</code>	Do not print anything except error messages
<code>--noexec</code>	Do not run the embedded installation script
<code>--target dir</code>	Sets the default installation directory

1.4 Manual installation

You can also install Unitex/GramLab manually from the source distribution package. Download it from:

<http://releases.unitexgramlab.org/latest-rc/source>

The downloaded file will be named something like:

```
Unitex-GramLab-3.1rc-source-distribution.zip
```

Decompress it into a directory called for example `Unitex3.1rc`, which should preferably be created in the `Program Files` directory, and which will be the Unitex system directory.

If your computer runs one of the following operating systems, the installation is finished: Windows (32-bit, 64-bit), GNU/Linux (i686, x86_64) and OS X (10.7+). (If it runs another Unix-like OS, like FreeBSD, or has another processor architecture, like ARM, go into the `App/install` directory and type:

```
sh setup
```

This script checks if Java is installed, compiles the C++ core sources, sets up the Unitex and GramLab personal working directories and creates some desktop shortcuts.¹⁾

When the installation is finished, the Unitex system directory contains several subdirectories, one of which is called `App`.

- On Windows: the `App` directory contains files named `Unitex.jar` and `GramLab.jar`. They are the Java files that launch the graphical interfaces. Double-click on one of them to start Unitex or GramLab (see 1.5). To facilitate launching the interfaces, you may want to add shortcuts to these files on the desktop.
- On Linux or OS X: the `App` directory contains two shell scripts named `Unitex` and `GramLab`. Launch one of them to start Unitex or GramLab (see 1.5). If you have run the `setup` script, it should have added shortcuts to these files on the desktop.

1.5 First use

If you work on Windows, the program will ask you to choose a personal working directory, which you can change later in "Info>Preferences...>Directories". To create a directory, click on the icon showing a file (see figure 1.5).

If you are using Linux or OS X, the program will automatically create a personal working directory called `/unitex` in your `$HOME` directory.

¹If you want to compile only the C++ core sources, extract the files from the source distribution package, go into the `Src/C++/build` directory and type `make install`.

The personal working directory, or user's directory, allows you to save your personal Unitex data. For each language that you will be using, the program will copy the root directory of that language to your working directory, except the dictionaries. You can then modify your copy of the files without risking to damage the system files stored in the Unitex system directory.

Figure 1.3: First use under Windows

Figure 1.4: First use under Linux

1.6 Adding new languages

There are two different ways to add languages. If you want to add a language that is to be accessible by all users, you have to copy the corresponding directory to the Unitex system directory, for which you will need to have the access rights (this might mean that you need to ask your system administrator to do it). On the other hand, if you are the only user working with the language, you can also copy the directory to your working directory. You can work with this language without it being shown to other users.

Figure 1.5: Creating the personal working directory

1.7 Uninstalling Unitex

No matter which operating system you are working with, it is sufficient to delete the Unitex system directory to completely delete all the program files. Under Windows you may have to delete the shortcut to `Unitex.jar` if you have created one on your desktop. The same has to be done on Linux, if you have created an alias.

1.8 Unitex for developers

If you are a programmer, you may be interested in linking your code to the C++ core of Unitex. To facilitate such operation, you can compile Unitex as a dynamic library that contains all Unitex functions, except `mains`, of course. The page <http://docs.unitexgramlab.org/projects/unitex-library/en/latest/> contains documentation about the library. The C++ core of Unitex contains source code for Java JNI, Ruby and Microsoft .NET bindings. The page <https://github.com/patwat/python-unitex> contains Python bindings.

Under Linux/OS X, type:

```
make LIBRARY=yes
```

and you will obtain a library named `libunitex.so`. If you want to produce a Windows DLL named `unitex.dll`, use the following commands:

Windows: `make SYSTEM=windows LIBRARY=yes`

Cross-compiling with mingw32: `make SYSTEM=mingw32 LIBRARY=yes`

In all cases, you will also obtain a program named `Test_lib(.exe)`. If everything worked fine, this program should display the following:

```
Expression converted.
Reg2Grf exit code: 0
```

```

Chapter 2

Loading a text

One of the main functionalities of Unitex is to search a text for expressions. To do that, texts have to undergo a set of preprocessing steps that normalize non-ambiguous forms and split the text in sentences. Once these operations are performed, the electronic dictionaries are applied to the texts. Then one can search more effectively in the texts by using grammars.

This chapter describes the different steps for text preprocessing.

2.1 Selecting a language

When starting Unitex, the program asks you to choose the language in which you want to work (see figure 2.1). The languages displayed are the ones that are present in the Unitex system directory and those that are installed in your personal working directory. If you use a language for the first time, Unitex copies the system directory for this language to your working directory, except for the dictionaries in order to save disk space.

WARNING: If you already have a working directory for a given language, Unitex won't try to copy system data into it. So, if an update has modified a resource file other than a dictionary, you will have to copy by yourself this file, or to delete your working directory for this language, and let Unitex rebuild it properly.

Choosing the language allows Unitex to find certain files, for example the alphabet file. You can change the language at any time by choosing "Change Language..." in the "Text" menu. If you change the language, the program will close all windows related to the current text, if there are any. The active language is indicated in the title bar of the graphical interface.

2.2 Text formats

Unitex works with Unicode texts. Unicode is a standard that describes a universal character code. Each character is given a unique number, which allows for representing texts without having to take into account the proprietary codes on different machines and/or operating

Figure 2.1: Language selection when starting Unitex

systems. Unitex uses a two-byte representation of the Unicode 3.0 standard, called Unicode Little-Endian (for more details, see [16]).

Texts that come with Unitex are already in Unicode format. If you try to open a text that is not in Unicode, the program proposes to convert it (see figure 2.2). This conversion is based on the current language: if you are working in French, Unitex proposes to convert your text¹ assuming that it is coded using a French code page. By default, Unitex proposes to either replace the original text or to rename the original file by inserting `.old` at the beginning of its extension. For example, if one has an ASCII file named `biniou.txt`, the conversion process will create a copy of this ASCII file named `biniou.old.txt`, and will replace the contents of `biniou.txt` with its equivalent in Unicode.

Figure 2.2: Automatic conversion of a non-Unicode text

If the encoding suggested by default is not correct or if you want to rename the file differently than with the suffix `.old`, you must use the "More options..." button. This allows you to choose source and target encodings of the documents to be converted (see figure 2.3). By default, the selected source encoding is that which corresponds to the current language and the destination encoding is Unicode Little-Endian. You can modify these choices by selecting any source and target encodings. Thus, if you wish, you can convert your data into other

¹Unitex also proposes to automatically convert graphs and dictionaries that are not in Unicode Little-Endian.

encodings, as for example UTF-8 in order for instance to create web pages. The button "Add Files" enables you to select the files to be converted. The button "Remove Files" makes it possible to remove a list of files erroneously selected. The button "Transcode" will start the conversion of all the selected files. If an error occurs with a file is processed (for example, a file which is already in Unicode), the conversion continues with the next file.

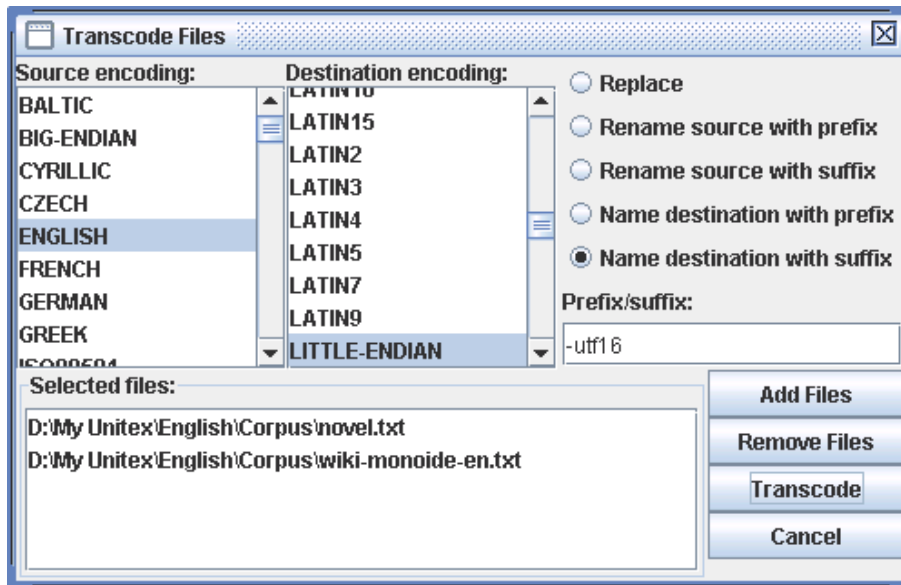

Figure 2.3: Transcoding files

To obtain a text in the right format, you can also use a text processor like the free software from OpenOffice.org ([75]) or Microsoft Word, and save your document with the format "Unicode text". In OpenOffice Writer, you have to choose the "Coded Text (*.txt)" format and then select the "Unicode" encoding in the configuration window as shown on figure 2.5.

Figure 2.4: Saving in Unicode with OpenOffice Writer

By default, the encoding proposed on a PC is always Unicode Little-Endian. The texts thus obtained do not contain any formatting information anymore (fonts, colors , etc.) and are ready to be used with Unitex.

You can change the default encoding to UTF16LE, UTF16BE or UTF8 in the 'Encoding' tab via the Preference command in the Info menu. This encoding is valid for the current language only.

Figure 2.5: Setting the default encoding for current language

2.3 Editing text files

For small texts, you also have the possibility of using the text editor integrated into Unitex, accessible via the "Open..." command in the "File Edition" menu". This editor offers search and replace functionalities for the texts and dictionaries handled by Unitex. To use it, click on the "Find" icon. You will then see a window divided into three parts. The "Find" part corresponds to the usual search operations. If you open a text split into sentences, you can base your search on sentence numbers in the "Find Sentence" part. Lastly, the "Search Dictionary" part, visible in figure 2.6, enables you to carry out operations concerning the electronic dictionaries. In particular, you can search by specifying if it concerns inflected forms, lemmas, grammatical and semantic and/or inflectional codes. Thus, if you want to search for all the verbs which have the semantic feature τ , which indicates transitivity, you just have to search for τ by clicking on "Grammatical code". You will get the matching entries without confusion with all the other occurrences of the letter τ .

2.4 Opening a text

Unitex deals with several types of documents. The files with the extension `.snt` are text files preprocessed by Unitex which are ready to be manipulated by the different system functions. You can also load raw files ending with `.txt`, or XML and HTML files. To open any of these files, click on "Open..." in the "Text" menu. You can there choose the file type ("Raw Unicode Texts", "XML files", "HTML files", "Unitex Texts"). If you open XML or HTML files, `foo.xml` for example, it will be preprocessed in order to remove non textual content. This will produce a `foo.xml.txt` file containing only the textual content of the original file. The resulting `.txt` file will be processed to produce a `.snt` file

Figure 2.6: Searching an electronic dictionary for the semantic feature t

Figure 2.7: Text Menu

2.5 Preprocessing a text

After a text is selected, Unitex offers to preprocess it. Text preprocessing consists of performing the following operations: normalization of separators, splitting into sentences, normalization of non-ambiguous forms, tokenization and application of dictionaries. If you choose not to preprocess the text, it will nevertheless be normalized and tokenized, since these operations are necessary for all further Unitex operations. It is always possible to carry out the preprocessing later by clicking on "Preprocess Text..." in the "Text" menu.

Figure 2.8: Opening a Unicode text

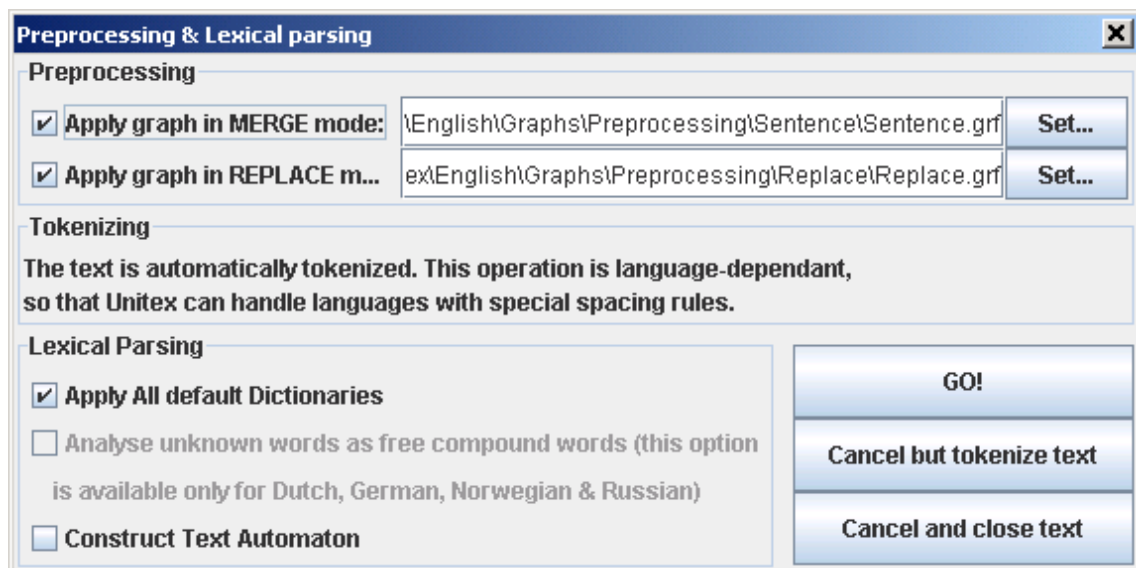

Figure 2.9: Preprocessing Window

If you choose to preprocess the text, Unitex proposes to parameterize it as in the window shown in figure 2.9. The option "Apply FST2 in MERGE mode" is used to split the text into

sentences. The option "Apply FST2 in REPLACE mode" is used to make replacements in the text, especially for the normalization of non-ambiguous forms. With the option "Apply All default Dictionaries" you can apply dictionaries in the DELA format (Dictionnaires Electroniques du LADL). The option "Analyze unknown words as free compound words" is used in Norwegian for correctly analyzing compound words constructed via concatenation of simple forms. Finally, the option "Construct Text Automaton" is used to build the text automaton. This option is deactivated by default, because it consumes a large amount of memory and disk space if the text is too large. The construction of the text automaton is described in chapter 7.

NOTE: If you click on "Cancel but tokenize text", the program will carry out the normalization of separators and split the text into tokens. Click on "Cancel and close text" to cancel the operation.

2.5.1 Normalization of separators

The standard separators are the space, the tab and the newline characters. There can be several separators following each other, but since this isn't useful for linguistic analyses, separators are normalized according to the following rules:

- a sequence of separators that contains at least one newline is replaced by a single newline
- all other sequences of separators are replaced by a single space.

The distinction between space and newline is maintained at this point because the presence of newlines may have an effect on the process of splitting the text into sentences. The result of the normalization of a text named `my_text.txt` is a file in the same directory as the `.txt` file and is named `my_text.snt`.

NOTE: When the text is preprocessed using the graphical interface, a directory named `my_text_snt` is created immediately after normalization. This directory, called text directory, contains all the data associated with this text.

2.5.2 Splitting into sentences

Splitting texts into sentences is an important preprocessing step since this helps in determining the units for linguistic processing. The splitting is used by the text automaton construction program. In contrast to what one might think, detecting sentence boundaries is not a trivial problem. Consider the following text:

The family has urgently called Dr. Martin.

The full stop that follows *Dr* is followed by a word beginning with a capital letter. Thus it may be considered as the end of the sentence, which would be wrong. To avoid the kind of problems caused by the ambiguous use of punctuation, grammars are used to describe

Figure 2.10: Sentence splitting grammar for French

the different contexts for the end of a sentence. Figure 2.10 shows an example grammar for sentence splitting (for French sentences).

When a path of the grammar recognizes a sequence in the text and when this path produces the sentence delimiter symbol $\{S\}$, this symbol is inserted into the text. For example, one of the paths shown in figure 2.10 recognizes the sequence consisting of a question mark and a word beginning with a capital letter and inserts the symbol $\{S\}$ between the question mark and the following word. The following text:

What time is it? Eight o' clock.

will be converted to:

What time is it ?{S} Eight o' clock.

A grammar for end-of-sentence detection may use the following special symbols, or meta-symbols:

- $\langle E \rangle$: empty word, or epsilon. Recognizes the empty sequence;

- <WORD>: recognizes any sequence of letters;
- <LOWER>: recognizes any sequence of letters in lower case;
- <UPPER>: recognizes any sequence of letters in upper case;
- <FIRST>: recognizes any sequence of letters that begins with an upper case letter;
- <NB>: recognizes any sequence of digits (1234 is recognized but not 1 234);
- <PNC>: recognizes the punctuation symbols ; , ! ? : and the inverted exclamation points and question marks in Spanish and some Asian punctuation letters;
- <^>: recognizes a newline;
- #: prohibits the presence of a space.

Earlier codes for <WORD>, <LOWER>, <UPPER> and <FIRST> were respectively <MOT>, <MIN>, <MAJ> and <PRE>. They can still be used for backward compatibility of the system with existing graphs. Though there are no current plans to remove these codes, it is recommended to avoid them in graphs designed to be used with more recent versions,² so that the number of lexical masks in use does not increase uselessly.

By default, the space is optional between two boxes. If you want to prohibit the presence of the space you have to use the special character #. At the opposite, if you want to force the presence of the space, you must use the sequence " ". Lower and upper case letters are defined by an alphabet file (see chapter 14). For more details on grammars, see chapter 5. For more information about sentence boundary detection, see [21]. The grammar used here is named `Sentence.fst2` and can be found in the following directory:

```
/(working directory)/(language)/Graphs/Preprocessing/Sentence
```

This grammar is applied to a text with the `Fst2Txt` program in MERGE mode. This has the effect that the output produced by the grammar, in this case the symbol {S}, is inserted into the text. This program takes a `.snt` file and modifies it.

2.5.3 Normalization of non-ambiguous forms

Certain forms present in texts can be normalized (for example, the English sequence "I'm" is equivalent to "I am"). You may want to replace these forms according to your own needs. However, you have to be careful that the forms normalized are unambiguous or that the removal of ambiguity has no undesirable consequences.

For instance, if you want to normalize "O'clock" to "on the clock", it would be a bad idea to replace "O" by "on the ", because a sentence like:

John O'Connor said: "it's 8 O'clock"

²From version 3.1beta, revision 4072, October 2, 2015.

would be replaced by the following incorrect sentence:

John on the Connor said: "it's 8 on the clock"

Thus, one needs to be very careful when using the normalization grammar. One needs to pay attention to spaces as well. For example, if one replaces "'re" by "are", the sentence:

You're stronger than him.

will be replaced by:

Youare stronger than him.

To avoid this problem, one should explicitly insert a space, *i.e.* replace "'re" by " are".

The accepted symbols for the normalization grammar are the same as the ones allowed for the sentence splitting grammar. The normalization grammar is called `Replace.fst2` and can be found in the following directory:

```
/(working directory)/(language)/Graphs/Preprocessing/Replace
```

As in the case of sentence splitting, this grammar is applied using the `Fst2Txt` program, but in `REPLACE` mode, which means that input sequences recognized by the grammar are replaced by the output sequences that are produced. Figure 2.11 shows a grammar that normalizes verbal contractions in English.

2.5.4 Splitting a text into tokens

Some languages, in particular Asian languages, use separators that are different from the ones used in western languages. Spaces can be forbidden, optional, or mandatory. In order to better cope with these particularities, Unifex splits texts in a language dependent way. Thus, languages like English are treated as follows:

A token can be:

- the sentence delimiter `{S}`;
- the stop marker `{STOP}`. This token is a special one that can NEVER be matched in any way by a grammar. It can be used to bound elements in a corpus. For instance, if a corpus is made of news separated by `{STOP}`, it will be impossible that a grammar matches a sequence that overlaps the end of a news and the beginning of the following news;
- a lexical tag `{aujourd'hui, .ADV}`;
- a contiguous sequence of letters (the letters are defined in the language alphabet file);
- one (and only one) non-letter character, *i.e.* all characters not defined in the alphabet file of the current language; if it is a newline, it is replaced by a space.

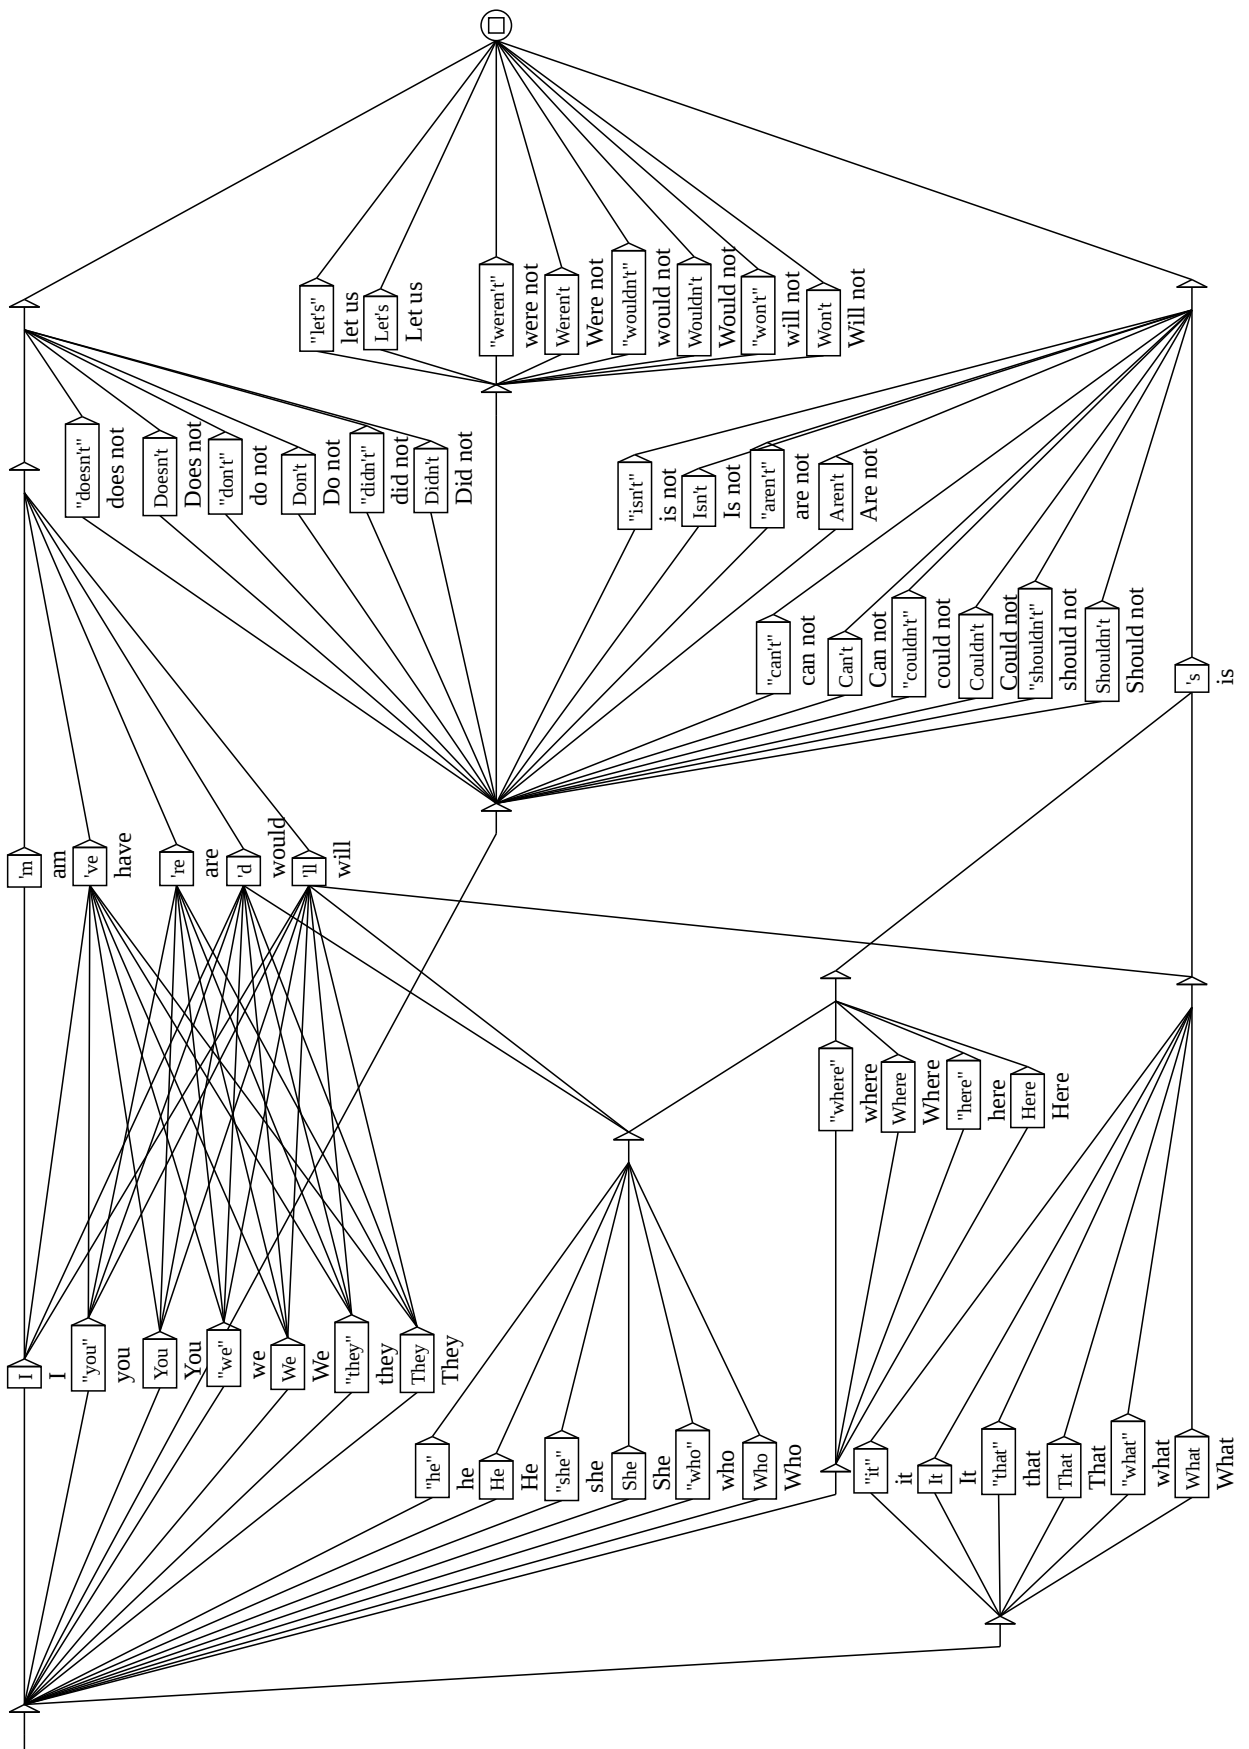

Figure 2.11: Normalization of English verbal contractions

For other languages, tokenization is done on a character by character basis, except for the sentence delimiter `{S}`, the `{STOP}` marker and lexical tags. This simple tokenization is fundamental for the use of `Unitex`, but limits the optimization of search operations for patterns.

Regardless of the tokenization mode, newlines in a text are replaced by spaces. Tokenization is done by the `Tokenize` program. This program creates several files that are saved in the text directory:

- `tokens.txt` contains the list of tokens in the order in which they are found in the text;
- `text.cod` contains an integer array; every integer corresponds to the index of a token in the file `tokens.txt`;
- `tok_by_freq.txt` contains the list of tokens sorted by frequency;
- `tok_by_alph.txt` contains the list of tokens in alphabetical order;
- `stats.n` contains some statistics about the text.

Tokenizing the text:

A cat is a cat.

returns the following list of tokens: `A SPACE cat is a .`

You will observe that tokenization is case sensitive (*A* and *a* are two distinct tokens), and that each token is listed only once. Numbering these tokens from 0 to 5, the text can be represented by a sequence of numbers (integers) as described in the following table:

Token number	0	1	2	1	3	1	4	1	2	5
Corresponding token	<i>A</i>		<i>cat</i>		<i>is</i>		<i>a</i>		<i>cat</i>	<i>.</i>

Table 2.1: Representation of the text *A cat is a cat.*

For more details, see chapter [14](#).

2.5.5 Applying dictionaries

Applying dictionaries consists of building the subset of dictionaries consisting only of forms that are present in the text. Thus, the result of applying an English dictionary to the text *Igor's father in law is ill* produces a dictionary of the following simple words:

Count	Token
82311	
8435	,
5772	the
3500	of
3161	"
2584	and
2454	.
2374	to
2343	{S}
2301	-
1578	a
1340	his
1172	in
802	with
792	I
786	which
771	he
744	was
744	that
738	as
714	;
563	by

Figure 2.12: Tokens of an English text sorted by frequency

```

father, .N+Hum:s
father, .V:W:P1s:P2s:P1p:P2p:P3p
ill, .A
ill, .ADV
ill, .N:s
in, .A
in, .N:s
in, .PART
in, .PREP
is, be.V:P3s
is, i.N:p
law, .N:s
law, .V:W:P1s:P2s:P1p:P2p:P3p
s, .N:s

```

as well as a dictionary of compound words consisting of a single entry:

```
father in law, .N+NPN+Hum+z1:s
```

Since the sequence *Igor* is neither a simple English word nor a part of a compound word, it is treated as an unknown word. The application of dictionaries is done through the program `Dico`. The three files produced (`d1f` for simple words, `d1c` for compound words and `err` for unknown words) are placed in the text directory. The `d1f` and `d1c` files are called text dictionaries.

As soon as the dictionary look-up is finished, Unitex displays the sorted lists of simple, compound and unknown words found in a new window. Figure 2.13 shows the result for an English text.

Figure 2.13: Result after applying dictionaries to an English text

It is also possible to apply dictionaries without preprocessing the text. In order to do this, click on "Apply Lexical Resources..." in the "Text" menu. Unitex then opens a window (see figure 2.14) in which you can select the list of dictionaries to apply.

The list "User resources" lists all dictionaries present in the directory (current language)/Dela of the user. The dictionaries installed in the system are listed in the scroll list named "System resources". Use the <Ctrl+click> combination to select several dictionaries. System dictionaries will be applied prior to user dictionaries. Within the system or user list, you can fix the order of dictionaries using the up and down arrows, as

Figure 2.14: Parameterizing the application of dictionaries

shown on figure 2.14. The button "Set Default" allows you to define the current selection of dictionaries as the default. This default selection will then be used during preprocessing if you activate the option "Apply All default Dictionaries". If you right-click on a dictionary name, the associated documentation, if any, will be displayed in the lower frame of the window.

2.5.6 Analysis of compound words in Dutch, German, Norwegian and Russian

In certain languages like Norwegian, German and others, it is possible to form new compound words by concatenating together other words. For example, the word *aftenblad* meaning *evening journal* is obtained by combining the words *aften* (*evening*) et *blad* (*journal*). The PolyLex program parses the list of unknown words after the application of dictionaries and tries to analyze each of these words as a compound word. If a word has at least one analysis as a compound word, it is removed from the list of unknown words and the lines produced for this word are appended to the simple word text dictionary.

2.6 Opening a tagged text

A tagged text is a text containing words with lexical tags enclosed in braces:

I do not like the {square bracket,.N} sign! {S}

Such tags can be used to avoid ambiguities. In the previous example, it will be impossible to match *square bracket* as the combination of two simple words.

However, the presence of these tags can alter the application of preprocessing graphs. To avoid complications, you can use the "Open Tagged Text..." command in the "Text" menu. With it, you can open a tagged text and skip the application of preprocessing graphs, as shown on Figure 2.15.

Figure 2.15: Preprocessing a tagged text

Chapter 3

Dictionaries

3.1 The DELA dictionaries

The electronic dictionaries distributed with Unitex use the DELA syntax (Dictionnaires Electroniques du LADL, LADL electronic dictionaries). This syntax describes the simple and compound lexical entries of a language with their grammatical, semantic and inflectional information. We distinguish two kinds of electronic dictionaries. The one that is used most often is the dictionary of inflected forms DELAF (DELA de formes Fléchies, DELA of inflected forms) or DELACF (DELA de formes Composées Fléchies, DELA of compound inflected forms) in the case of compound forms. The second type is a dictionary of non-inflected forms called DELAS (DELA de formes simples, simple forms DELA) or DELAC (DELA de formes composées, compound forms DELA).

Unitex programs make no distinction between simple and compound form dictionaries. We will use the terms DELAF and DELAS to distinguish the inflected and non-inflected dictionaries, no matter they contain simple word, compound words or both.

3.1.1 The DELAF format

Entry syntax

An entry of a DELAF is a line of text terminated by a newline that conforms to the following syntax:

```
apples,apple.N+conc:p/this is an example
```

The different elements of this line are:

- `apples` is the inflected form of the entry; it is mandatory;

- `apple` is the canonical form (lemma) of the entry. For nouns and adjectives (in French), it is usually the masculine singular form; for verbs, it is the infinitive. This information may be left out as in the following example:

```
apple, .N+Conc:s
```

This means that the canonical form is the same as the inflected form. The canonical form is separated from the inflected form by a comma.

- `N+Conc` is the sequence of grammatical and semantic information. In our example, `N` designates a noun, and `Conc` indicates that this noun designates a concrete object (see table 3.2).

Each entry must have at least one grammatical or semantic code, separated from the canonical form by a period. If there are more codes, these are separated by the `+` character.

- `:p` is an inflectional code which indicates that the noun is plural. Inflectional codes are used to describe gender, number, declension, and conjugation. This information is optional. An inflectional code is made up of one or more characters that represent one information each. Inflectional codes have to be separated by the `:"` character, for instance in an entry like the following:

```
hang, .V:W:P1s:P2s:P1p:P2p:P3p
```

The `:` character is interpreted in OR semantics. Thus, `:W:P1s:P2s:P1p:P2p:P3p` means "infinitive", or "1st person singular present", or "2nd person singular present", etc. (see table 3.3) Since each character represents one information, you must not use the same character more than once. In this way, encoding the past participle using the code `:PP` would be exactly equivalent to using `:P` alone;

- `/this is an example` is a comment. Comments are optional and are introduced by the `/` character. These comments are left out when the dictionaries are compressed.

IMPORTANT REMARK: It is possible to use the full stop and the comma within a dictionary entry. In order to do this they have to be escaped using the `\` character:

```
1\,000,one thousand.NUMBER
United Nations,U\.N\..ACRONYM
```

WARNING: Each character is taken into account within a dictionary line. For example, if you insert spaces, they are considered to be a part of the information. In the following line:

hath,have.V:P3s /old form of 'has'

The space that precedes the / character will be considered to be part of a 4-character inflectional code.

It is possible to insert comments into a DELAF or DELAS dictionary by starting the line with a / character. Example:

```
/ 'English' designates a pool spin
English, .N+z3:s
```

Compound words with spaces or dashes

Certain compound words like *acorn-shell* can be written using spaces or dashes. In order to avoid duplicating the entries, it is possible to use the = character. At the time when the dictionary is compressed, the `Compress` program checks for each line if the inflected or canonical form contains a non-escaped = character. If this is the case, the program replaces this by two entries: one where the = character is replaced by a space, and one where it is replaced by a dash. Thus, the following entry:

```
acorn=shells,acorn=shell.N:p
```

is replaced by the following entries:

```
acorn shells,acorn shell.N:p
acorn-shells,acorn-shell.N:p
```

NOTE: If you want to keep an entry that includes the = character, escape it using \ as in the following example:

```
E\=mc2, .FORMULA
```

This replacement is done when the dictionary is compressed. In the compressed dictionary, the escaped = characters are replaced by simple =. As such, if a dictionary containing the following lines is compressed:

```
E\=mc2, .FORMULA
acorn=shell, .N:s
```

and if the dictionary is applied to the following text:

Formulas like $E=mc^2$ have nothing to do with acorn-shells.

you will get the following lines in the dictionary of compound words of the text:

```
E=mc2, .FORMULA
acorn-shells, .N:p
```

Entry Factorization

Several entries containing the same inflected and canonical forms can be combined into a single one if they also share the same grammatical and semantic codes. Among other things this allows us to combine identical conjugations for a verb:

```
bottle, .V:W:P1s:P2s:P1p:P2p:P3p
```

If the grammatical and semantic information differ, one has to create distinct entries:

```
bottle, .N+Conc:s  
bottle, .V:W:P1s:P2s:P1p:P2p:P3p
```

Some entries that have the same grammatical and semantic entries can have different meanings, as it is the case for the French word *poêle* that describes a stove or a type of sheet in the masculine sense and a kitchen instrument in the feminine sense. You can thus distinguish the entries in this case:

```
poêle, .N+z1:fs/ poêle à frire  
poêle, .N+z1:ms/ voile, linceul; appareil de chauffage
```

NOTE: In practice, this distinction has the only consequence that the number of entries in the dictionary increases.

For the different programs that make up Unix these entries are equivalent to:

```
poêle, .N+z1:fs:ms
```

Whether this distinction is made is thus left to the maintainers of the dictionaries.

3.1.2 The DELAS Format

The DELAS format is very similar to the one used in the DELAF. The only difference is that there is only a canonical form followed by grammatical and/or semantic codes. The canonical form is separated from the different codes by a comma. There is an example:

```
horse, N4+An1
```

The first grammatical or semantic code will be interpreted by the inflection program as the name of the grammar used to inflect the entry. The entry of the example above indicates that the word *horse* has to be inflected using the grammar named N4. It is possible to add inflectional codes to the entries, but the nature of the inflection operation limits the usefulness of this possibility. For more details see below in section 3.5.

3.1.3 Dictionary Contents

The dictionaries provided with Unitex contain descriptions of simple and compound words. These descriptions indicate the grammatical category of each entry, optionally their inflectional codes, and various semantic information. The following tables give an overview of some of the different codes used in the Unitex dictionaries. These codes are the same for almost all languages, though some of them are special for certain languages (*i.e.* code for neuter nouns, etc.).

Code	Description	Examples
A	adjective	fabulous, broken-down
ADV	adverb	actually, years ago
CONJC	coordinating conjunction	but
CONJS	subordinating conjunction	because
DET	determiner	each
INTJ	interjection	eureka
N	noun	evidence, group theory
PREP	preposition	without
PRO	pronoun	you
V	verb	overeat, plug-and-play

Table 3.1: Frequent grammatical codes

Code	Description	Example
z1	general language	joke
z2	specialized language	floppy disk
z3	very specialized language	serialization
Abst	abstract	patricide
An1	animal	horse
An1Coll	collective animal	flock
Conc	concrete	chair
ConcColl	collective concrete	rubble
Hum	human	teacher
HumColl	collective human	parliament
t	transitive verb	kill
i	intransitive verb	agree

Table 3.2: Some semantic codes

NOTE: The descriptions of tense in table 3.3 correspond to French. Nonetheless, the majority of these definitions can be found in other languages (infinitive, present, past participle, etc.).

In spite of a common base in the majority of languages, the dictionaries contain encoding

particularities that are specific for each language. Thus, as inflectional codes vary a lot between different languages, they are not described here. For a complete description of all codes used within a dictionary, we recommend that you contact the author of the dictionary directly.

Code	Description
m	masculine
f	feminin
n	neuter
s	singular
p	plural
1, 2, 3	1st, 2nd, 3rd person
P	present indicative
I	imperfect indicative
S	present subjunctive
T	imperfect subjunctive
Y	present imperative
C	present conditional
J	simple past indicative
W	infinitive
G	present participle
K	past participle
F	future indicative

Table 3.3: Common inflectional codes

However, these codes are not exclusive. A user can introduce his own codes and create his own dictionaries. For example, for educational purposes one could use a marker "faux-ami" (*false friend*) in a French dictionary:

```
blessier, .V+faux-ami/injure
casque, .N+faux-ami/helmet
journée, .N+faux-ami/day
```

It is equally possible to use dictionaries to add extra information. Thus, you can use the inflected form of an entry to describe an abbreviation and the canonical form to provide the complete form:

```
DNA, DeoxyriboNucleic Acid.ACRONYM
LADL, Laboratoire d'Automatique Documentaire et Linguistique.ACRONYM
UN, United Nations.ACRONYM
```

3.2 Looking up a word in a dictionary

You can look up a word in one or several dictionaries by two means :

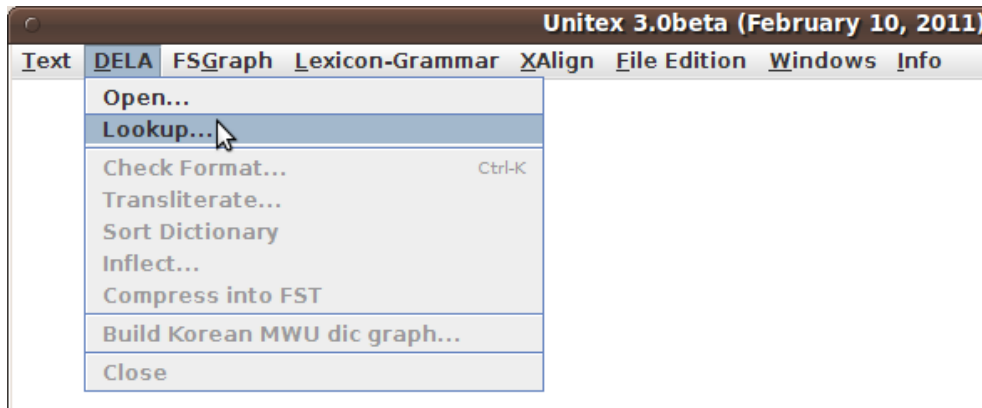

Figure 3.1: "DELA" Menu

If you have opened a dictionary, the displayed window contains a field where you can enter a word to search. If the word appears in the dictionary, the Find Button will highlight the first entry that matches it. If there is several entries for this word, you can browse all matches by clicking on the two arrow buttons.

Figure 3.2: Looking up for a word in a dictionary

You can also look up a word in several dictionaries by clicking on the Lookup button of the

DELA menu. You can then select the dictionaries in which you want to look up the word you have entered.

Figure 3.3: Looking up for a word in several dictionaries

3.3 Checking dictionary format

When dictionaries become large, it becomes tiresome to check them by hand. Unitex contains the program `CheckDic` that automatically checks the format of DELAF and DELAS dictionaries.

This program verifies the syntax of the entries. For each malformed entry the program outputs the line number, the content of the line and an error message. Results are saved in the file `CHECK_DIC.TXT` which is displayed when the verification is finished. In addition to eventual error messages, the file also contains the list of all characters used in the inflectional and canonical forms, the list of grammatical and semantic codes, and the list of inflectional codes that appear in the dictionary. The character list makes it possible to verify that the characters used in the dictionary are consistent with those in the alphabet file of the language. Each character is followed by its value in hexadecimal notation.

The code lists can be used to check that there are no typing errors in the codes of the dictionary.

The `CheckDic` program works with non-compressed dictionaries, *i.e.* the files in text format. The general convention is to use the `.dic` extension for these dictionaries. In order to check the format of a dictionary, you first open it by choosing "Open..." in the "DELA" menu. Let's load the dictionary as in figure 3.4. Then, click on "Check Format..." in the "DELA" menu. A window like in figure 3.5 is opened. You must select the type of dictionary you want to check. After checking the dictionary in Figure 3.4, results are presented as shown in Figure 3.6.

Figure 3.4: Dictionary example

Figure 3.5: Checking a dictionary

The first error is caused by a missing period. The second, by the fact that no comma was found after the end of an inflected form. The third error indicates that the program didn't find any grammatical or semantic codes.

3.4 Sorting

Unitex uses the dictionaries without having to worry about the order of the entries. When displaying them it is sometimes preferable to sort the dictionaries. The sorting depends on a number of criteria, first of all on the language of the text. Therefore the sorting of a Thai dictionary is done according to an order different from the alphabetical order. So different in fact that Unitex uses a sorting procedure developed specifically for Thai (see chapter 13).

For European languages the sorting is usually done according to the lexicographical order, although there are some variants. Certain languages like French treat some characters as equivalent. For example, the difference between the characters *e* and *é* is ignored if one wants to compare the words *manger* et *mangés* because the contexts *r* and *s* allow to decide the order. The difference is only taken into account when the contexts are identical, as they are when comparing *pêche* and *pèche*.

To allow for such effect, the `SortTxt` program uses a file which defines the equivalence of characters. This file is named `Alphabet_sort.txt` and can be found in the user directory for the current language. By default the first lines of this file for French look like this:

```

Check Results
Line 1: unexpected end of line
agreeably,ADV
Line 2: unexpected end of line
agreed.INTJ
Line 4: empty grammatical or semantic code
ah,.
-----
-----  Stats  -----

s

```

Figure 3.6: Results of checking

```

AÀÂÃäàâä
Bb
CÇcç
Dd
EÉÈÊËëéèë

```

Characters in the same line are considered equivalent if the context permits. If two equivalent characters must be compared, they are sorted in the order they appear in from left to right. As can be seen from the extract above, there is no difference between lower and upper case. Accents and the cedille character are ignored as well.

To sort a dictionary, open it and then click on "Sort Dictionary" in the "DELA" menu. By default, the program always looks for the file `Alphabet_sort.txt`. If that file doesn't exist, the sorting is done according to the character indices in the Unicode encoding. By modifying that file, you can define your own sorting order.

NOTE: After applying the dictionaries to a text, the files `dlf`, `dlc` and `err` are automatically sorted using this program.

3.5 Automatic inflection

3.5.1 Inflection of simple words

As described in section 3.1.2, a line in a DELAS consists of a canonical form and a sequence of grammatical or semantic codes:

```

aviatrix,N4+Hum
matrix,N4+Math
radix,N4

```

The first code is used to determine the grammatical code of the entry as well as the name of the grammar used to inflect the canonical form. There are two possible forms:

- N4: grammar name=`N4.fst2`, grammatical code=N (longest letter prefix)
- N(NC_XXX): grammar name=`NC_XXX.fst2`, grammatical code=N

These inflectional grammars will automatically be compiled if needed. In the example above, all entries will be inflected by a grammar named N4.

In order to inflect a dictionary, click on "Inflect..." in the "DELA" menu. The window in figure 3.7 allows you to specify the directory in which inflectional grammars are found. By default, the subdirectory `Inflection` of the directory for the current language is used. You can also specify the kind of words your DELAS is supposed to contain. If an entry is found that does not correspond to your choice, an error message will be displayed.

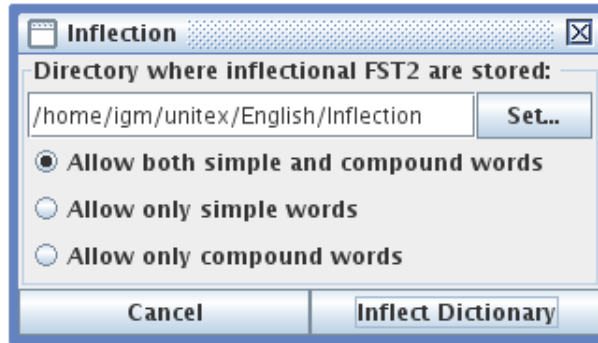

Figure 3.7: Configuration of automatic inflection

Figure 3.8: Inflectional grammar N4

Figure 3.8 shows an example of an inflectional grammar. The paths describe the suffixes to add or to remove to get to an inflected form from a canonical form, and the outputs (text in bold under the boxes) are the inflectional codes to add to a dictionary entry.

In our example, two paths are possible. The first does not modify the canonical form and adds the inflectional code **:s**. The second deletes a letter with the **L** operator, then adds the **ces** suffix and adds the inflectional code **:mp**. Here are the operators that can be used:

- **L** (left) removes a letter from the entry.
- **R** (right) restores a letter to the entry. In French, many verbs of the first group are conjugated in the present singular of the third person form by removing the **r** of the infinitive and changing the 4th letter from the end to **è**: *peler* → *pèle*, *acheter* → *achète*, *gérer* → *gère*, etc. Instead of describing an inflectional suffix for each verb (**LLLLèle**, **LLLLète** and **LLLLère**), the **R** operator can be used to describe it in one way: **LLLLèRR**.
- **C** (copy) duplicates a letter in the entry and moves everything on its right by one position. In cases like *permitted* or *hopped*, we see a duplication of the final consonant of the verb. To avoid writing an inflectional graph for every possible final consonant, one can use the **C** operator to duplicate any final consonant.

- D (delete) deletes a letter, shifting anything located on the right of this letter. For instance, if you want to inflect the Romanian word `europeean` into `europeeni`, you must use the sequence `LDRi`. `L` will move the cursor on the `a`, `D` will delete the `a`, shifting the `n` on the left, and then `Ri` will restore the `n` and add an `i`.
- U (unaccent) removes the accent of the current character, if any. For instance the sequence `LLUx` applied to the word `manges` produces the inflected form `mangex`, since `U` has turn the `e` into a `e`.
- P (uppercase) uppercases the initial letter of the stack. For instance, the sequence `Px` will turn `foo` into `Foox`.
- W (lowercase) lowercases the initial letter of the stack.
- `<R=?>` replaces the initial letter of the stack by the letter `?`.
- `<I=?>` inserts the letter `?` before the initial letter of the stack.
- `<X=n>` removes the first `n` letters of the stack.

There are also two operators dedicated to Korean:

- J removes a Jamo letter. If the current character is a Hangul syllab character, this character is first replaced by the equivalent Jamo sequence, and then, the last Jamo letter is removed. If the current character is neither a Jamo nor a Hangul, and error is raised.
- . (latin dot) inserts a syllab bound. As a side effect, if the top of the stack contains Jamo letters, they are first recombined into a Hangul character.

In the example below, the inflection of `choose` is shown. The sequence `LLDRRn` describes the form `chosen`:

- Step 0: the canonical form is copied on the stack, and the cursor is set behind the last letter:

- Step 1: the cursor is moved one position to the left:

- Step 2: the cursor is moved one position to the left again:

- Step 3: one character is deleted; everything to the right of the cursor is shifted one position to the left:

- Step 4: the cursor is moved to the right:

- Step 5: and to the right again:

- Step 6: the character n is pushed on the stack:

When all operations have been fulfilled, the inflected form consists of all letters before the cursor (here chosen).

The inflection program explores all paths of the inflectional grammar and tries all possible forms. In order to avoid having to replace the names of inflectional grammars by the actual grammatical codes to be used in the dictionary, the program replaces these names by the longest prefixes made of letters. Thus, N4 is replaced by N. By choosing the inflectional grammar names carefully, one can construct a ready-to-use dictionary.

Figure 3.9 shows the dictionary we get after the inflection of our DELAS example.

Figure 3.9: Result of automatic inflection

3.5.2 Advanced inflection operators

In some languages the inflection process can modify the root of the word. Several operators have been developed in order to facilitate this type of treatment. They allow to find and remove a suffix of the word \bar{w} to be inflected. It is also possible to store a factor of this suffix by using a special variable ($\$$ or \mathcal{L}). These operators can take the following forms:

- $\langle X\$Y \rangle$: Starting from the end of the word \bar{w} we are looking for the suffix Y . Then, we search for the **rightmost** occurrence of X which strictly precedes that of Y . The $\$$ variable then contains the **shortest factor** ($\$$ shortest) of \bar{w} strictly between X and Y ($\bar{w} = U.X.\$.Y$)¹. The $\langle X\$Y \rangle$ operator strips $X.\$.Y$ from \bar{w} and sets $\$$. After it has been applied, the string left in the stack is U , and the $\$$ variable can be used in the rest of the path.
- $\langle X\mathcal{L}Y \rangle$: Starting from the end of the word \bar{w} we are looking for the suffix Y . Then, we search for the **leftmost** occurrence of X which strictly precedes that of Y . The \mathcal{L} variable then contains the **longest factor** (\mathcal{L} ongest) of \bar{w} strictly between X and Y ($\bar{w} = U.X.\mathcal{L}.Y$).
- $\langle X \rangle$: If there is no variable, we search for X as a suffix of \bar{w} ($\bar{w} = U.X$).
- $\langle \$Y \rangle$: If the X factor is absent, the **shortest factor** $\$$ is the first letter which strictly precedes Y .
- $\langle \mathcal{L}Y \rangle$: If the X factor is absent, the **longest factor** \mathcal{L} is the prefix of \bar{w} so that $\bar{w} = \mathcal{L}.Y$.

To illustrate the use of these operators, let us consider the French verb *reprendre*:

¹The point represents here the concatenation operation.

Word	Operator	Variable	Result
reprendre	<re>		reprend
reprendre	<\$>	\$ = e	reprendr
reprendre	<£>	£ = reprendre	ε
reprendre	<re\$re>	\$ = nd	rep
reprendre	<re£re>	£ = prend	
reprendre	<\$re>	\$ = d	repre
reprendre	<re\$>	\$ = ε	reprendre
reprendre	<£re>	£ = reprend	ε
reprendre	<re£>	£ = prendre	re

The MultiFlex program allows you to use ten variables of type \$ whose names are \$,\$1,...,\$9 and ten variables of type £ whose names are £,£1,...,£9. Moreover, both types of variables can be mixed in a same operator. Thus the operator <£3re\$7re> applied to the french verb *reprendre* gives back : £3 = rep et \$7 = nd.

In the verbs *accélérer*, *sécher*, the second person of the present tense can be generated by the operation <é\$er>è\$es :

accélérer <é\$er> → accél \$ = r + è\$es → accélères
 sécher <é\$er> → s \$ = ch + è\$es → sèche

Note that the factor \$ which remains in the inflected form is of variable length (r, ch). The inflection of the verbs *accélérer* and *sécher* cannot be done with classical stack operators within the same operation. Two different operations (-4RèCes, -5RèCes) are needed. The graph shown in figure 3.10 inflects verbs like *accélérer* and *sécher* in the present tense.

Figure 3.10: Inflection graph for verbs like *accélérer*, *sécher*

The inflected forms of the verbs *accélérer* and *sécher* are :

```
accélère, accélérer.V:P1s:P3s
accélèrent, accélérer.V:P3p
accélères, accélérer.V:P2s
accélérez, accélérer.V:P2p
accélérons, accélérer.V:P1p
sèche, sécher.V:P1s:P3s
sèchent, sécher.V:P3p
sèches, sécher.V:P2s
séchez, sécher.V:P2p
séchons, sécher.V:P1p
```

The doubling of some letters during the inflection process can be done with the operator \$. For example the adjective *tranquil* has two forms in the comparative and two in the superlative. The graph in figure 3.11 can produce these forms.

Figure 3.11: Inflection graph for adjectives like *tranquil*

Below are the inflected forms for the adjective *tranquil* :

```
tranquil, tranquil.A
tranquiler, tranquil.A:C
tranquilest, tranquil.A:S
tranquiller, tranquil.A:C
tranquillest, tranquil.A:S
```

In some languages, some inflected forms have a prefix added before the root like the formation of the past participle in German. The joint use of operators \mathcal{L} et \mathcal{S} allows to inflect the german verb *sprechen* (to speak) in the present tense and the past participle as shown in the graph in figure 3.12.

Figure 3.12: Inflection graph for verbs like *sprechen*

The inflection forms of the verb *sprechen* :

```

gesprochen, sprechen.V:K
spreche, sprechen.V:P1s
sprechen, sprechen.V:P1p:P3p:W
sprichst, sprechen.V:P2p:P2s
spricht, sprechen.V:P3s

```

In order to inflect the phrasal verb *aussprechen* two variables of type \$ should be used. Figure 3.13 shows a graph with two variables \$1 and \$2.

Figure 3.13: Inflection graph for verbs like *aussprechen*

Here are the inflection forms of the verb *aussprechen* :

```

ausgesprochen, aussprechen.V:Kms
aussprechen, aussprechen.V:W
spreche aus, aussprechen.V:P1s
sprichst aus, aussprechen.V:P2p
sprichst aus, aussprechen.V:P2s
spricht aus, aussprechen.V:P3s
sprechen aus, aussprechen.V:P3p
sprechen aus, aussprechen.V:P1p

```

Semantic codes

In some languages, there are inflectional features that actually correspond to semantic ones, like for instance markers for the passive form. Such codes may not appear as inflectional ones, but rather as semantic ones. To do that and produce semantic codes, you have to insert a plus sign at the beginning of the output of a box. The box must only contain the semantic code preceded by a plus, as shown on Figure 3.14.

Figure 3.14: An inflection grammar with a semantic code

3.5.3 Inflection of compound words

See chapter 11.

3.5.4 Inflection of Semitic languages

Semitic languages like Arabic or Hebrew are inflected in a way not easily representable with the inflection operators described above. Their morphology obeys a different logic: words are inflected according to *consonant skeletons*. The inflection process combines this skeleton with vowels. Specific operators have been implemented for Semitic languages, and some of them may be useful also for languages outside the Semitic family, such as Tagalog.

First, let us see a case where we encode only the consonants in the lemma field of the DELAS entry:

ktb, \$V31-123

The $\$$ sign before the grammatical code indicates that the inflection grammar is in the Semitic mode, and the form `ktb` in the lemma field is the consonant skeleton. Figure 3.15 shows the toy grammar `V31-123.grf` that illustrates how the Semitic mode works. The inflection grammars use the Buckwalter++ transliteration of the Arabic script (cf. Section 3.6).

Figure 3.15: A toy inflection grammar in the Semitic mode

The Semitic mode obeys the following rules:

1. All standard inflection operators can be used (L, R, etc.).
2. A digit stands for a letter in the lemma field (1 for the first, 2 for the second, etc.). In our example, 1, 2 and 3 will respectively stand for k, t and b. If you want to access to a letter after the ninth one, you must protect its index with angles like `<10>`.

The DELAF output for this grammar is:

```
yakotubu,ktb.V:aI3ms
```

If we encode only the consonants in the lemma field and two entries have the same consonants but differ in the vowels, we must encode the vowels in the inflection grammars:

```
Hsb,$V3au // to count, Hasaba, yaHosubu
Hsb,$V3ii // to think, Hasiba, yaHosibu
```

In order to copy the complete lemma field, use the `<LEMMA>` operator. A box with this operator retrieves the complete lemma field but does not depend on the number of letters in the field. This operator is useful for Arabic nouns and adjectives where masculine forms are generated by inserting vowels in the consonantal skeleton, whereas feminine forms are obtained by appending suffixes (Figure 3.16). In this example, both consonants and vowels are encoded in the lemma field.

The `<n.LEMMA>` operator copies the lemma from the n th position to the end. For example, in some Arabic nouns, the short vowel of the first syllable alternates: a/u, a/i or u/i, as in `nufaAyap/nifaAyap` "rubbish". The inflection grammar of Fig. 3.17 produces both variants with u and with i as inflected forms of `nufaAyap`.

In Tagalog, an Austronesian language spoken in the Philippines and that uses commonly infixes and reduplication for inflection, `<LEMMA>` and `<n.LEMMA>` may be used to produce verb tenses. The toy inflection grammar of Fig. 3.18 produces the perfect `kumain`, future `kakain` and imperfect `kumakain` of the verb `kain` "eat".

Lexical Entry تَلْمِيذٌ تَلَامِيذَةٌ tilomiyoJ,\$N400-g-FvEvLvB-FaEaLiBap-1234

Figure 3.16: An inflection grammar in the Semitic mode with the <LEMMA> operator

Figure 3.17: An inflection grammar in the Semitic mode with the <n.LEMMA> operator

3.6 Transliterating Arabic dictionaries

When Arabic linguists analyse dictionaries in order to spot errors, reading in the Arabic script is simple and efficient. However, when they create inflectional grammars (Section 3.5), parts of Arabic words occur in the same box as morphosyntactic information encoded in the Latin alphabet, and in this context, switching from right-to-left Arabic script to left-to-right Latin alphabet is a real hassle. With Unitex, you can encode your inflectional grammars entirely in the Latin alphabet, by using the Buckwalter++ transliteration, a one-to-one mapping between a Unicode encoding of Arabic script and Latin letters (cf. [74], Section 3.2, pages 4–6). The Buckwalter++ transliteration is defined by the table of Fig. 3.19 and 3.20. Unitex provides a tool to internally transliterate DELAS and DELAF Arabic dictionaries to and from Buckwalter++ encoding (Fig. 3.21). This tool is accessible through the DELA

Figure 3.18: A toy inflection grammar for Tagalog in the Semitic mode

menu.

3.7 Compression

Unitex applies compressed dictionaries to the text. The compression reduces the size of the dictionaries and speeds up the lookup. This operation is done by the `Compress` program. This program takes a dictionary in text form as input (for example `my_dico.dic`) and produces two files:

- `my_dico.bin` contains the minimal automaton of the inflected forms of the dictionaries;
- `my_dico.inf` contains the codes extracted from the original dictionary.

The minimal automaton in the `my_dico.bin` file is a representation of inflected forms in which all common prefixes and suffixes are factorized. For example, the minimal automaton of the words `me, te, se, ma, ta et sa` can be represented by the graph shown in Figure 3.22.

To compress a dictionary, open it and click on "Compress into FST" in the "DELA" menu. The compression is independent from the language and from the content of the dictionary. The messages produced by the program are displayed in a window that is not closed automatically. You can see the size of the resulting `.bin` file, the number of lines read and the number of inflectional codes created. Figure 3.23 shows the result of the compression of a dictionary of simple words.

The resulting files are compressed to about 95% for dictionaries containing simple words and 50% for those with compound words.

When the Semitic mode (3.5.4) has been heavily used to inflect a dictionary, a specific variant of the compression algorithm may reduce the size of the resulting .bin and .inf files. In order to use it, either declare the language as being a Semitic one in the global preferences

Figure 3.23: Results of a compression

by checking the “Semitic language” option in “Preferences > Language and Presentation”, or use the Compress program in command line with the `--semitic` option.

3.8 Applying dictionaries

Dictionaries can be applied (1) after pre-processing or (2) by explicitly clicking on “Apply Lexical Resources” in the “Text” menu (see section 2.5.5).

Unitex can manipulate compressed dictionaries (`.bin`) and dictionary graphs (`.fst2`). We will now describe the rules for applying dictionaries in detail. Dictionary graphs will be described in section 3.8.3.

3.8.1 Priorities

The priority rule says that if a word in a text is found in a dictionary, this word will not be taken into account by dictionaries with lower priority.

This allows for eliminating a part of ambiguity when applying dictionaries. For example, the French word *par* has a nominal interpretation in the golf domain. If you don’t want to use this meaning, it is sufficient to create a filter dictionary containing only the entry `par, .PREP` and to apply this with highest priority. This way, even if simple word dictionaries contain different entries, they will be ignored given the priority rule.

There are three priority levels. The dictionaries whose names without extension end with `-` have the highest priority; those that end with `+` have the lowest one. All other dictionaries are applied with medium priority. The order in which dictionaries with the same priority are applied does not matter. On the command line, the command:

```
Dico ex.snt alph.txt ctr+.bin cities-.bin rivers.bin regions-.bin
```

will apply the dictionaries in the following order (`ex.snt` is the text to which the dictionaries are applied, and `alph.txt` is the alphabet file used):

1. `cities-.bin`
2. `regions-.bin`
3. `rivers.bin`
4. `ctr+.bin`

3.8.2 Application rules for dictionaries

Besides the priority rule, the application of dictionaries respects upper case letters and spaces. The upper case rule is as follows:

- if there is an upper case letter in the dictionary, then an upper case letter has to be in the text;
- if a lower case letter is in the dictionary, there can be either an upper or lower case letter in the text.

Thus, the entry `peter, .N:fs` will match the words `peter`, `Peter` et `PETER`, while `Peter, .N+firstName` only recognizes `Peter` and `PETER`. Lower and upper case letters are defined in the alphabet file passed to the `Dico` program as a parameter.

Respecting white space is a very simple rule: For each sequence in the text to be recognized by a dictionary entry, it has to have exactly the same number of spaces. For example, if the dictionary contains `aujourd'hui, .ADV`, the sequence `Aujourd' hui` will not be recognized because of the space that follows the apostrophe.

3.8.3 Dictionary graphs

The `Dico` program can also apply dictionary graphs. Dictionary graphs, by default,² conform to the following rule: if applied by `Locate` in `MERGE` mode, they must produce output sequences that are valid DELAF lines. When they are applied to a text, they attach the DELAF lexical labels to the sequences.

Figure 3.24 shows a graph that recognizes chemical elements. We can observe a first advantage of graphs over usual dictionaries: we can force case with double quotes. Thus, this graph will correctly match `Fe` but not `FE`, while this restriction cannot be specified in a normal DELAF.

²Morphological dictionary-graphs are an exception (section 3.8.4).

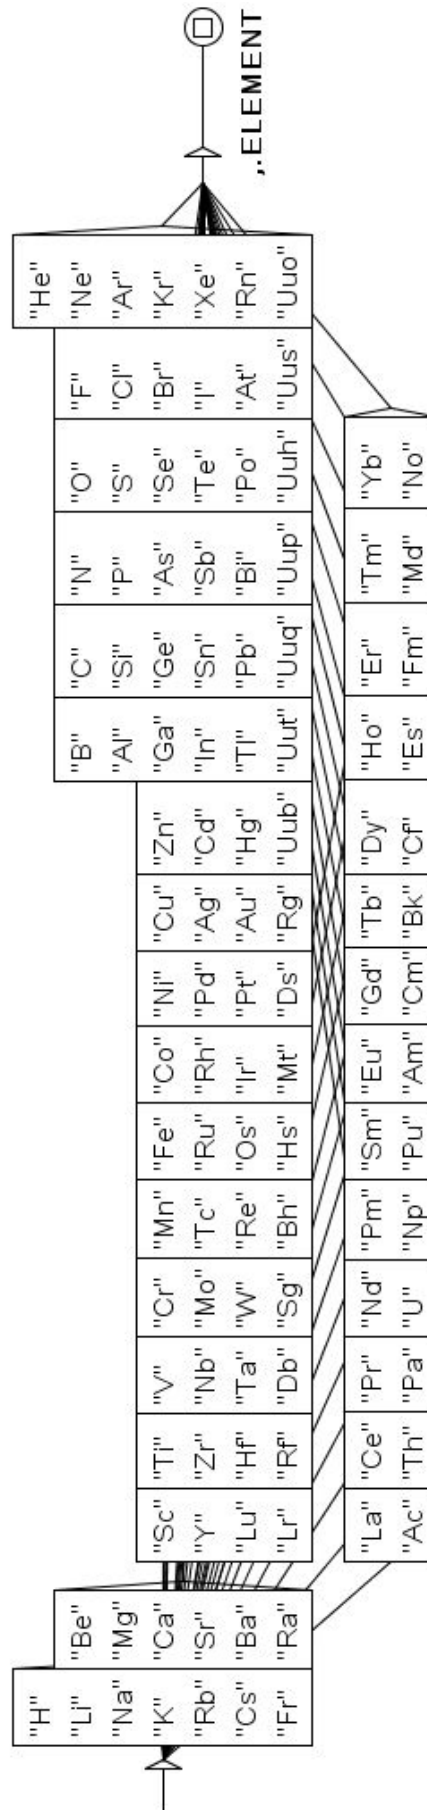

Figure 3.24: Dictionary graph of chemical elements

Another advantage of dictionary graphs is that they can use results given by previous dictionaries. Thus, it is possible to apply the standard dictionary, and then tag as proper names all the unknown words that begin with an uppercase letter, thanks to graph `NPr+` shown in figure 3.25. The `+` in the graph name gives to it a low priority, so that it will be applied after the standard dictionary. This graph works with words that are still unknown after the application of the standard dictionary. Square brackets stand for a context definition. For more information about contexts, see section 6.3.

Figure 3.25: Dictionary graph that tags unknown words beginning with an uppercase letter as proper names

Since dictionary graphs are applied using the engine of `Locate`, they have exactly the same properties than syntactic graphs. So, you can use morphological filters (section 4.7) and/or the morphological mode (section 6.4). For instance, the graph shown on Figure 3.26 uses morphological filters to recognize roman numerals. Note that it also uses contexts in order to avoid recognizing uppercase letters in some contexts.

By default, dictionary graphs are applied in `MERGE` mode. If you want to apply them in `REPLACE` mode, you must suffix graph names with `-r`. This can be combined with the `+` and `-` priority marks:

```
bagpipe-r.fst2 McAdam-r-.fst2 phtirius-r+.fst2
```

Exporting produced entries as a morphological-mode dictionary

Dictionary entries produced by dictionary graphs are looked up by the `Locate` program when it comes across lexical masks involving dictionary lookup.

However, this functionality is restricted when the lexical mask is in morphological mode (section 6.4). Dictionary graphs cannot be declared as being morphological-mode dictionaries in the usual way (section 6.4.3), because they are not `.bin` files. When in morphological mode, lexical masks involving dictionary lookup do not trigger lookup of dictionary graphs. To compensate for this, there are several solutions.

- Consider invoking the dictionary graph from the part of the graph which is in morphological mode.
- Unitex internally generates a dictionary of the forms recognized in the text by a dictionary graph. If the name of the dictionary graph contains the `b` switch (see Naming conventions below), Unitex includes this internal dictionary among morphological-mode dictionaries, so that it is looked up when the `Locate` program comes across lexical masks in morphological mode. But this solution works only for forms recognised in

Figure 3.26: Dictionary graph of roman numerals

the text by the dictionary graph during initial application of dictionaries (section 3.8), and not for forms that appear in the text only as token parts.

If you add *z* instead of *b*, then the dictionary internally generated for the text is compressed immediately, and can be looked up when other dictionary graphs are applied later.

Naming conventions

The whole naming scheme for dictionary graphs is as follows:

```
name(-XYZ) ([-+]) .fst2
```

where:

- *X* is in [*rRmM*]: *r* means REPLACE mode; *M* means MERGE mode (default);
- *Y* is in [*bBzZ*]: option that rules the production of a morphological-mode dictionary (see above Exporting produced entries as a morphological-mode dictionary);
- *Z* is in [*aAllsS*]: *a* means that the graph will be applied in "All matches" mode; *l* means "Longest matches" mode (default); *s* means "Shortest matches" mode.

3.8.4 Morphological dictionary-graphs

In a dictionary graph, by default, each path must output a lexical entry to be added in the text dictionaries. In a morphological dictionary-graph, each path must output a sequence of one or more tags enclosed in braces and conforming to the syntax of a DELAF line (section 3.1.1). The output of such graphs will be used as special input for the construction of the text automaton. We call them ‘morphological dictionary-graphs’ because their main utility is to introduce new morphological analyses in the text automaton, using the morphological mode (see section 6.4). This functionality is helpful for agglutinative languages like Korean. To allow the use of a graph as a morphological dictionary-graph, declare it with a slash (/) as the first character of its output, as in Figure 3.27.

Figure 3.27: Example of a morphological dictionary-graph

The rule is simple: any output of a dictionary graph that begins with a slash will be added to the file `tags.ind`, located in the text directory. This file is used by the `Txt2Fst2` program in order to add interpretations into the text automaton. The grammar of Figure 3.27 matches words made of the prefix `un` followed by an adjective. If we apply it as a dictionary graph, we obtain new paths in the text automaton, as shown on Figure 3.28. Note that when two tags correspond to analyses within the same token, the link between them is displayed with a dashed line.

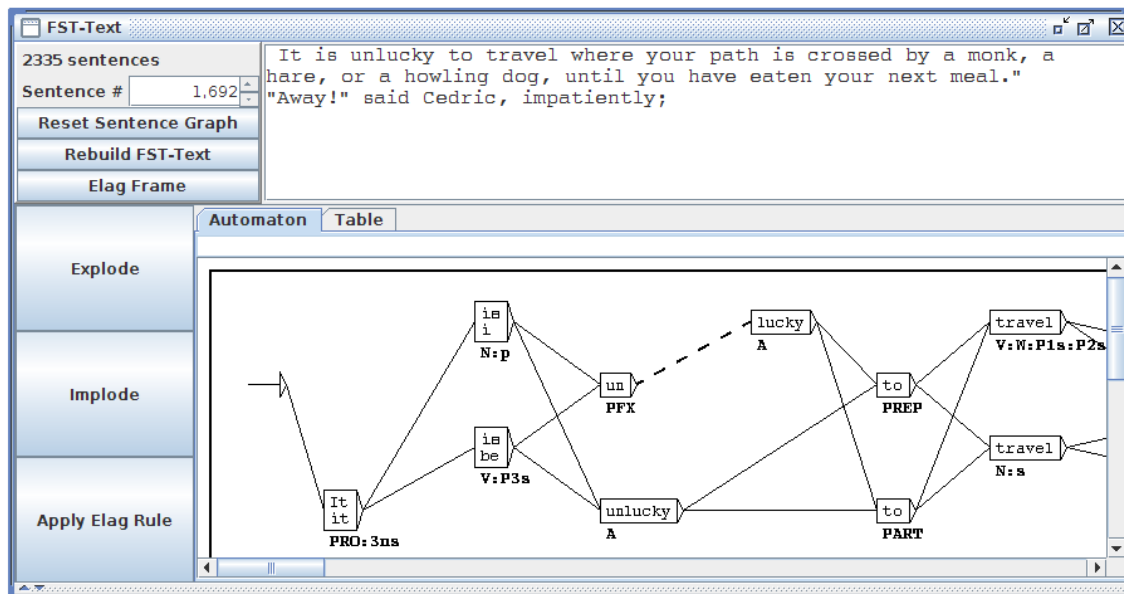

Figure 3.28: Path added by a morphological dictionary-graph

3.9 Bibliography

Table 3.4 gives some references for electronic dictionaries with simple and compound words. For more details, see the references page on the Unitex website:

Chapter 4

Searching with regular expressions

This chapter describes how to search a text for simple patterns by using regular expressions.

4.1 Definition

The goal of this chapter is not to give an introduction on formal languages but to show how to use regular expressions in Unitex in order to search for simple patterns. Readers who are interested in a more formal presentation can consult the many works that discuss regular expression patterns.

A regular expression can be:

- a token (`book`) or a lexical mask (`<smoke.V>`);
- a particular position in the text : the beginning `{^}` or the end `{}`;
- the concatenation of two regular expressions (`he smokes`);
- the union of two regular expressions (`Pierre+Paul`);
- the Kleene star of a regular expression (`bye*`).

4.2 Tokens

In a regular expression, a token is defined as in [2.5.4](#) (page 36). Note that the symbols dot, plus, star, less than, opening and closing parentheses and double quotes have a special meaning. It is therefore necessary to precede them with an escape character `\` if you want to search for them. Here are some examples of valid tokens:

```
cat
\.
<N:ms>
{S}
```

By default, Unix is set up to let lower case patterns also find upper-case matches. It is possible to enforce case-sensitive matching using quotation marks. Thus, "peter" recognizes only the form `peter` and not `Peter` or `PETER`.

NOTE: in order to make a space obligatory, it needs to be enclosed in quotation marks.

4.3 Lexical masks

A lexical mask is a search query that matches tokens or sequences of tokens.

4.3.1 Special symbols

There are two kinds of lexical masks. The first category contains the special symbols or meta-symbols introduced in section 2.5.2 except for `<PNC>` and `<^>`. (The symbol `<PNC>`, which matches punctuation signs, is valid only during preprocessing; `<^>` matches a line feed, but since all line feeds have been replaced by spaces, this symbol cannot be useful anymore when searching for lexical masks.) The meta-symbols that can be used to search a text for patterns are the following:

- `<E>`: the empty word or epsilon. Matches the empty string;
- `<TOKEN>`: matches any token, except the space; used by default for morphological filters
- `<WORD>`: matches any token that consists of letters;
- `<LOWER>`: matches any lower-case token;
- `<UPPER>`: matches any upper-case token;
- `<FIRST>`: matches any token that consists of letters and starts with a capital letter;
- `<DIC>`: matches any word that is present in the dictionaries of the text;
- `<SDIC>`: matches any simple word in the text dictionaries;
- `<CDIC>`: matches any composed word in the dictionaries of the text;
- `<TDIC>`: matches any tagged token like `{XXX,XXX.XXX}`;
- `<NB>`: matches any contiguous sequence of digit (1234 is matched but not 1 234);
- `#`: prohibits the presence of space.

Earlier codes for `<WORD>`, `<LOWER>`, `<UPPER>` and `<FIRST>` were respectively `<MOT>`, `<MIN>`, `<MAJ>` and `<PRE>`. They can still be used for backward compatibility of the system with existing graphs. Though there are no current plans to remove these codes, it is

recommended to avoid them in graphs designed to be used with more recent versions,¹ so that the number of lexical masks in use does not increase uselessly.

NOTE: as described in section 2.5.4, NO meta can be used to match the {STOP} marker, not even <TOKEN>.

4.3.2 References to information in the dictionaries

The second kind of lexical masks refers to the information in the text dictionaries. The four possible forms are:

- <be>: matches all the entries that have *be* as canonical form. Note that this pattern is ambiguous if *be* is also a grammatical or semantic code;
- <be.>: matches all the entries that have *be* as canonical form. This pattern is not ambiguous as the previous one;
- <be.V>: matches all entries having *be* as canonical form and the grammatical code *V*;
- <V>: matches all entries having the grammatical code *V*. This pattern is as ambiguous as the first one. To remove the ambiguity, you can use either <.V> or <+V>;
- {*am,be.V*} or <*am,be.V*>: matches all the entries having *am* as inflected form, *be* as canonical form and the grammatical code *V*. This kind of lexical mask is only of interest if applied to the text automaton where all the ambiguity of the words is explicit. While executing a search on the text, that lexical mask matches the same as the simple token *am*.

4.3.3 Grammatical and semantic constraints

The references to dictionary information (*be, V*) in these examples are basic. It is possible to express more complex lexical masks by using several grammatical or semantic codes separated by the character +. If several codes are present, the character + means "and": an entry of the dictionary is only found if it has all the codes that are present in the mask. The mask <N+z1> thus recognizes the entries:

```
broderies, broderie.N+z1:fp
capitales européennes, capitale européenne.N+NA+Conc+HumColl+z1:fp
```

but not:

```
Descartes, René Descartes.N+Hum+NPropre:ms
habitué, .A+z1:ms
```

It is possible to exclude codes by preceding them with the character ~ instead of +. In order to be recognized, an entry has to contain all the codes required by the lexical mask and

¹From version 3.1beta, revision 4072, October 2, 2015.

none of the prohibited ones. For instance, `<A~z3>` matches the entries that have the code `A` without the code `z3` (cf. table 3.2).² If you want to refer to a code containing the character `~` you have to escape this character by preceding it with a `\`.

CHANGE NOTE: before version 2.1, the negation operator was the minus. If you want to preserve backward compatibility without modifying your graphs, you have to call `Locate` by hand with the `-g minus` option.

The syntax of lexical masks does not make any difference between grammatical codes (table 3.1) and semantic codes (table 3.2). In the DELAF dictionary format, grammatical codes are those that appear first and encode the part of speech, but in Unitex lexical masks, the order in which grammatical and semantic codes appear does not matter. The three following patterns are equivalent:

```
<N~Hum+z1>
<z1+N~Hum>
<~Hum+z1+N>
```

A lexical mask can contain a semantic code without a part-of-speech code.

NOTE: it is not possible to use a lexical mask that only has prohibited codes. `<~N>` and `<~A~z1>` are thus incorrect masks. However, you can express such constraints using contexts (see section 6.3).

4.3.4 Inflectional constraints

It is also possible to specify constraints about inflectional codes. These constraints have to be preceded by at least one grammatical or semantic code. They are represented in the same format as the inflectional codes in the dictionaries. Here are some French examples of lexical masks using inflectional constraints:

- `<A:m>` recognizes a adjective in the masculine;
- `<A:mp>` recognizes an adjective in the masculine plural.

An inflectional code is introduced by the `:` character and is made up of one or more characters, each of which represents one piece of information. Let us consider first the simple case of dictionary entries and masks which have exactly one inflectional code. In order to let a dictionary entry E be recognized by a mask M , it is necessary that the inflectional code of E contains all the characters of the inflectional code of M :

```
 $E$ =pretext, .V:P3p
 $M$ =<V:P3>
```

²If a word is described in the dictionaries by an entry with `A+z3` and another with only `A`, the word is matched by `<A+z3>` because of the former entry and by `<A~z3>` because of the latter.

The inflectional code $P3p$ of E contains both characters P and 3 . The code $P3$ is included in the code of E . Therefore, mask M recognizes entry E .

The order of the characters inside an inflectional code is without importance. All the grammatical and semantic codes must precede the inflectional codes.

If several inflectional codes are present in a lexical mask, the $:$ character means "or":

- $\langle A:mp:f \rangle$ matches both $\langle A:mp \rangle$ and $\langle A:f \rangle$; it recognizes adjectives in the masculine plural or in the feminine;
- $\langle V:2:3 \rangle$ recognizes a verb in the 2nd or 3rd person; that excludes all tenses that have neither a 2nd or 3rd person (infinitive, past participle and present participle) as well as the tenses that are conjugated in the first person.

In order to let a dictionary entry E be recognized by a mask M , it is necessary that at least one inflectional code of E contains all the characters of at least one inflectional code of M . Consider the following example:

```
E=pretext, .V:W:P1s:P2s:P1p:P2p:P3p
M=<V:P3s:P3>
```

No inflectional code of E contains the characters P , 3 and s at the same time. However, the code $P3p$ of E does contain both characters P and 3 . The code $P3$ is included in at least one code of E . Therefore, mask M recognizes entry E .

4.3.5 Negation of a lexical mask

It is possible to negate a lexical mask by placing the character $!$ immediately after the character \langle . Negation is possible with the masks $\langle \text{WORD} \rangle$, $\langle \text{LOWER} \rangle$, $\langle \text{UPPER} \rangle$, $\langle \text{FIRST} \rangle$,³ $\langle \text{DIC} \rangle$ as well as with the masks that carry grammatical, semantic or inflectional codes (*i.e.* $\langle !V\sim z3:P3 \rangle$). The masks $\#$ and $"$ are the negation of each other. The mask $\langle !\text{WORD} \rangle$ recognizes all tokens that do not consist of letters except for the sentence delimiter $\{S\}$ and the $\{\text{STOP}\}$ marker. Negation has no effect on $\langle \text{NB} \rangle$, $\langle \text{SDIC} \rangle$, $\langle \text{CDIC} \rangle$, $\langle \text{TDIC} \rangle$ and $\langle \text{TOKEN} \rangle$.

The negation is interpreted in a special way in the masks $\langle !\text{DIC} \rangle$, $\langle !\text{LOWER} \rangle$, $\langle !\text{UPPER} \rangle$ and $\langle !\text{FIRST} \rangle$.⁴ Instead of recognizing all forms that are not recognized by the mask without negation, these masks find only forms that are sequences of letters. Thus, the mask $\langle !\text{DIC} \rangle$ allows you to find all unknown words in a text. These unknown forms are mostly proper names, neologisms and spelling errors (cf. Figure 4.1).

The negation of a dictionary mask like $\langle V:G \rangle$ will match any word, except for those that are matched by this mask. For instance, $\langle !V:G \rangle$ will not match the word *being*, even if there are homonymic non-verbal entries in the dictionaries:

³And with their legacy counterparts $\langle \text{MOT} \rangle$, $\langle \text{MIN} \rangle$, $\langle \text{MAJ} \rangle$, $\langle \text{PRE} \rangle$. See Section 4.3.1.

⁴And with their legacy counterparts $\langle !\text{MIN} \rangle$, $\langle !\text{MAJ} \rangle$, $\langle !\text{PRE} \rangle$. See Section 4.3.1.

Figure 4.1: Result of the search for <!DIC>

```
being, .A
being, .N+Abst:s
being, .N+Hum:s
```

Here are some examples of lexical masks with the different types of constraints:

- <A~Hum:fs>: a non-human adjective in the feminine singular;
- <lire.V:P:F>: the verb *lire* in the present or future tense;
- <suis, suivre.V>: the word *suis* as inflected form of the verb *suivre* (as opposed to the form of the verb *être*);
- <facteur.N~Hum>: all nominal entries that have *facteur* as canonical form and that do not have the semantic code Hum;
- <!ADV>: all words that are not adverbs;
- <!WORD>: all tokens that are not made of letters (cf. figure 4.2). This mask does not recognize the sentence delimiter {S} and the special tag {STOP}.

4.4 Concatenation

There are three ways to concatenate regular expressions. The first consists in using the concatenation operator which is represented by the dot. Thus, the expression:

Figure 4.2: Result of a search for the pattern <!WORD>

<DET>.<N>

recognizes a determiner followed by a noun. The space can also be used for concatenation, as well as the empty string. The following expressions:

```
the <A> cat
the<A>cat
```

recognizes the token *the*, followed by an adjective and the token *cat*. The parenthesis are used as delimiters of a regular expression. All of the following expressions are equivalent:

```
the <A> cat
(the <A>)cat
the.<A>cat
(the).<A> cat
(the.(<A>)) (cat)
```

4.5 Union

The union of regular expressions is expressed by typing the character + between them. The expression

```
(I+you+he+she+it+we+they) <V>
```

recognizes a pronoun followed by a verb. If an element in an expression is optional, it is sufficient to use the union of this element and the empty word epsilon. Examples:

```
the (little+<E>) cat recognizes the sequences the cat and the little cat
(<E>+Anglo-).(French+Indian) recognizes French, Indian, Anglo-French and Anglo-Indian
```

4.6 Kleene star

The Kleene star, represented by the character `*`, allows you to recognize zero, one or several occurrences of an expression. The star must be placed on the right hand side of the element in question. The expression:

```
this is very* cold
```

recognizes *this is cold*, *this is very cold*, *this is very very cold*, etc. The star has a higher priority than the other operators. You have to use brackets in order to apply the star to a complex expression. The expression:

```
0, (0+1+2+3+4+5+6+7+8+9) *
```

recognizes a zero followed by a comma and by a possibly empty sequence of digits.

WARNING: It is prohibited to search for the empty word with a regular expression. If you try to search for `(0+1+2+3+4+5+6+7+8+9) *`, the program will raise an error as shown in figure 4.3.

Figure 4.3: Error message when searching for the empty string

4.7 Morphological filters

It is possible to apply morphological filters to the lexemes found. For that, it is necessary to immediately follow the lexeme found by a filter in double angle brackets:

```
lexical mask<<morphological pattern>>
```

The morphological filters are expressed as regular expressions in POSIX format (see [65] for the detailed syntax). Here are some examples of elementary filters:

- <<ss>>: contains *ss*
- <<^a>>: begins with *a*
- <<ez\$>>: ends with *ez*
- <<a.s>>: contains *a* followed by any character, followed by *s*
- <<a.*s>>: contains *a* followed by a sequence of any character, followed by *s*
- <<ss|tt>>: contains *ss* or *tt*
- <<[aeiouy]>>: contains a non accentuated vowel
- <<[aeiouy]{3,5}>>: contains a sequence of non-accentuated vowels whose length is between 3 and 5
- <<es?>>: contains *e* followed by an optional *s*
- <<ss[^e]?>>: contains *ss* followed by an optional character which is not *e*

It is possible to combine these elementary filters to form more complex filters:

- <<[ai]ble\$>>: ends with *able* or *ible*
- <<^(anti|pro)-?>>: begins with *anti* or *pro*, followed by an optional dash
- <<^([rst][aeiouy]){2,}\$>>: a word formed by 2 or more sequences beginning with *r*, *s* or *t* followed by a non-accentuated vowel
- <<^(^[l]|l[^e])>>: does not begin with *l* unless the second letter is an *e*, in other words, any word except the ones starting with *le*. Such constraints are better described using contexts (see section 6.3).

By default, a morphological filter alone is regarded as applying it to the lexical mask <TOKEN>, that means any token except space and {STOP}. On the other hand, when a filter follows a lexical mask immediately, it applies to what was recognized by the lexical mask. Here are some examples of such combinations:

- <V:K><<i\$>>: Past participle ending with *i*
- <CDIC><<->>: A compound word containing a dash
- <CDIC><< .* >>: a compound word containing at least two spaces
- <A:fs><<^pro>>: a feminine singular adjective beginning with *pro*
- <DET><<^(^[u]|(u[^n])|(un.+))>>: a (French) determiner different from *un*

- <!DIC><<es\$>>: a word which is not in the dictionary and which ends with *es*
- <V:S:T><<uiss>>: a verb in the past or present subjunctive, and containing *uiss*

NOTE: By default, morphological filters are subject to the same variations of case as lexical masks. Thus, the filter <<^b>> will recognize all the words starting with *b*, but also those which start with *B*. To force the matcher to respect case, add *_f_* immediately after the filter, e.g.: <<^b>>_f_.

4.8 Search

4.8.1 Search configuration

In order to search for an expression, first open a text (cf. chapter 2). Then click on "Locate Pattern..." in the "Text" menu. The window of figure 4.4 appears.

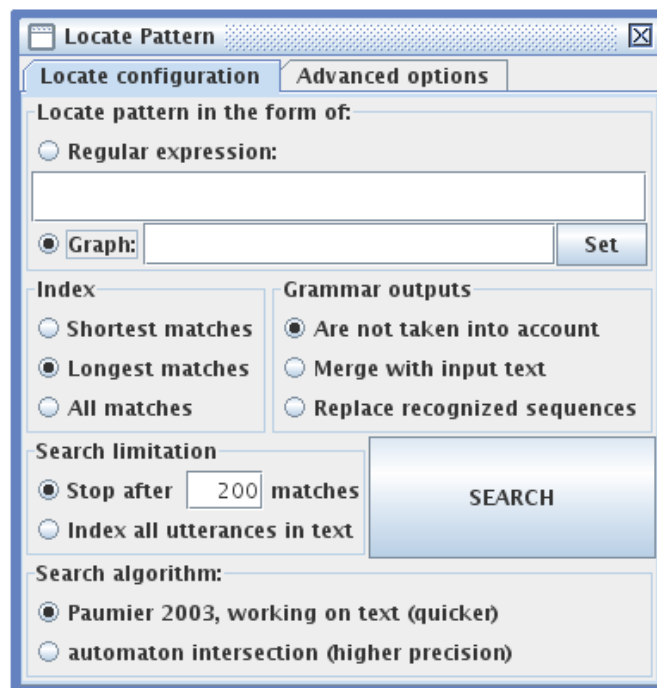

Figure 4.4: "Locate pattern" window

The "Locate pattern in the form of" box allows you to select regular expression or grammar. Click on "Regular expression".

The "Index" box allows you to select the recognition mode:

- "Shortest matches" : prefers shortest matches in case of nested sequences. For instance, if your grammar can recognize the sequences *a very hot chili* and *very hot*, the first one will be discarded;
- "Longest matches" : prefers longest matches (*a very hot chili* in our example). This is the default;
- "All matches" : outputs all recognized sequences.

The "Search limitation" box is used to limit the number of results to a certain number of occurrences. By default, the search is limited to the first 200 occurrences.

The options of the "Grammar outputs" box do not concern regular expressions. They are described in section 6.10. The same for options of tab "Advanced options" (see section 6.10.2).

In the "Search algorithm" frame, you can specify whether you want to perform the locate operation on the text using the `Locate` program or on the text automaton with `LocateTfst`. By default, search is done with the `Locate` program, as `Unitex` always did until now. If you want to use `LocateTfst`, please read dedicated section 7.7.

Enter an expression and click on "Search" in order to start the search. `Unitex` will transform the expression into a grammar in the `.grf` format. This grammar will then be compiled into a grammar of the `.fst2` format that will be used for the search.

4.8.2 Presentation of the results

When the search is finished, the window of figure 4.5 appears showing the number of matched occurrences, the number of recognized tokens and the ratio between this number and the total number of tokens in the text.

Figure 4.5: Search results

After clicking on "OK" you will see window 4.6 appear, which allows you to configure the presentation of the matched occurrences. You can also open this window by clicking on "Located Sequences..." in the "Text" menu. The list of occurrences is called a *concordance*.

Figure 4.6: Result display configuration

The "Modify text" box offers the possibility to replace the matched occurrences with the generated outputs. This possibility will be examined in chapter 6.

The "Extract units" box allows you to create a text file with all the sentences that do or do not contain matched units. With the button "Set File", you can select the output file. Then click on "Extract matching units" or "Extract unmatching units" depending on whether you are interested in sentences with or without matching units.

In the "Show matching sequences in context" box, you can select the length in characters of the left and right contexts of the occurrences that will be presented in the concordance. If an occurrence has less characters than its right context, the line will be completed with the necessary number of characters. If an occurrence has a length greater than that of the right context, it will be displayed completely.

NOTE: in Thai, the size of the contexts is measured in displayable characters and not in real characters. This makes it possible to keep the line alignment in the concordance despite the presence of diacritics that combine with other letters instead of being displayed as normal characters.

You can choose the sort order in the list "Sort According to". The mode "Text Order" displays the occurrences in the order of their appearance in the text. The other six modes allow you to sort in columns. The three zones of a line are the left context, the occurrence and the right context. The occurrences and the right contexts are sorted from left to right. The left contexts are sorted from right to left. The default mode is "Center, Left Col.". The concordance is generated in the form of an HTML file.

If a concordance reaches several thousands of occurrences, it is advisable to display it in a web browser (Firefox [11], Netscape [12], Internet Explorer, etc.) instead. Check "Use a web browser to view the concordance" (cf. figure 4.6). This option is activated by default if the number of occurrences is greater than 2000. You can configure which web browser to use by clicking on "Preferences..." in the menu "Info". Click on the tab "Language & Presentation" and select the program to use in the field "Html Viewer" (cf. figure 4.7).

If you choose to open the concordance in Unitex, you will see a window as shown on Figure 4.8. Occurrences react as hyperlinks. If you click on an occurrence, the text frame is opened and the corresponding sequence is highlighted. Moreover, if the text automaton is available and if this window is not iconified, the sentence automaton that contains the occurrence will be shown.

Figure 4.7: Selection of a web browser for displaying concordances

Figure 4.8: Example concordance

4.8.3 Statistics

If you select the “Statistics” tab in the “Located sequences..” frame, you will see the panel shown on figure 4.9. This panel allows you to get some statistics from the previously indexed sequences.

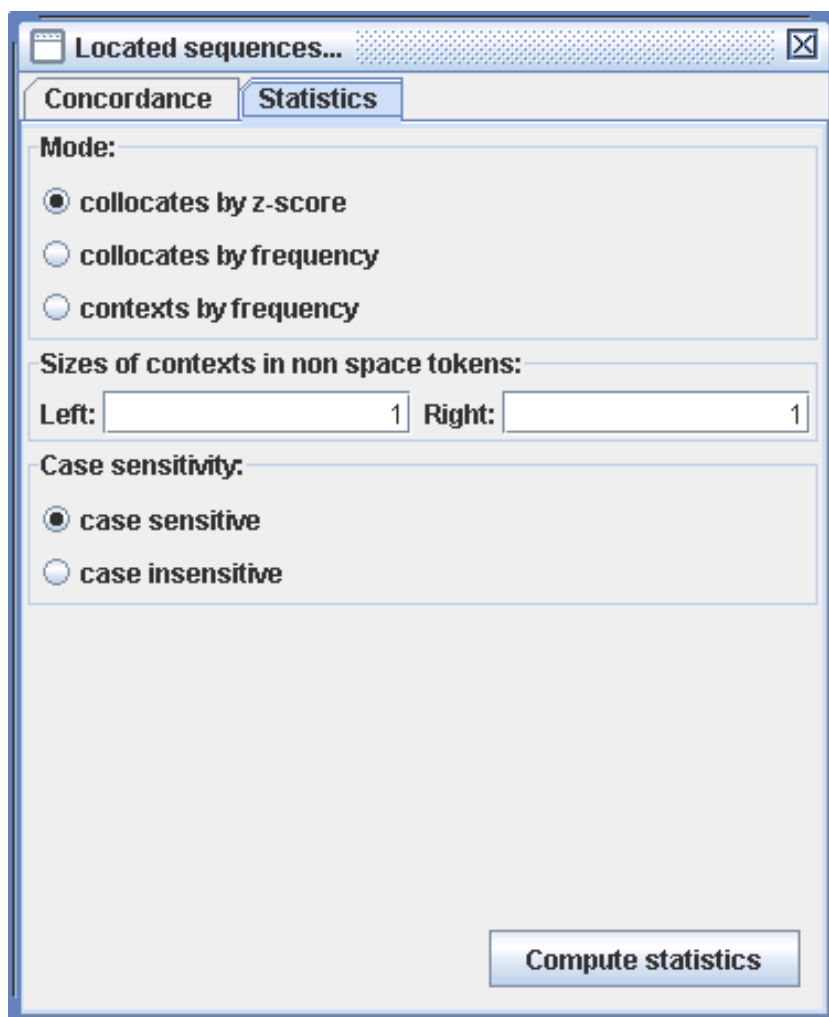

Figure 4.9: Statistics panel

In the “Mode” panel, you can select the kind of statistics you want:

- collocates by z-score: the previous one, plus some additional information (number of occurrences of the collocate in the match context and in the whole corpus, z-score of the collocate)
- collocates by frequency: shows the tokens that cooccur in the match context

- contexts by frequency: shows matches with left and right contexts (see below). “count” is the number of occurrences of a given match+context

In the second panel, you can set the length of left and right contexts to be used, in non space tokens. NOTE: this notion of context has nothing to do with contexts in grammars.

In the last panel, you can allow or not case variations. If you allow case variations, the and THE will be considered as a same token, and the count will be the sum of the counts of the and THE.

The following figures show the statistics computed in each mode for the query <have> on `ivanhoe.snt`.

Left context	Match	Right context	Occurrences

Chapter 5

Local grammars

Local grammars are a powerful tool to represent the majority of linguistic phenomena. The first section presents the formalism in which these grammars are represented. Then we will see how to construct and present grammars using Unitex.

5.1 The local grammar formalism

5.1.1 Algebraic grammars

Unitex grammars are variants of algebraic grammars, also known as context-free grammars. An algebraic grammar consists of rewriting rules. Below you see a grammar that matches any number of a characters:

$$\begin{aligned} S &\rightarrow aS \\ S &\rightarrow \varepsilon \end{aligned}$$

The symbols to the left of the rules are called *non-terminal symbols* since they can be replaced. Symbols that cannot be replaced by other rules are called *terminal symbols*. The items at the right side are sequences of non-terminal and terminal symbols. The epsilon symbol ε designates the empty word. In the grammar above, S is a non-terminal symbol and a a terminal (symbol). S can be rewritten as either an a followed by a S or as the empty word. The operation of rewriting by applying a rule is called *derivation*. We say that a grammar generates a word if there exists a sequence of derivations that produces that word. The non-terminal that is the starting point of the first derivation is called an *axiom*.

The grammar above also generates the word aa , since we can derive this word according to the axiom S by applying the following derivations:

Derivation 1: rewriting the axiom to aS

$$\underline{S} \rightarrow aS$$

Derivation 2: rewriting S at the right side of aS

$$S \rightarrow a\underline{S} \rightarrow aaS$$

Derivation 3: rewriting S to ε

$$S \rightarrow aS \rightarrow aa\underline{S} \rightarrow aa$$

We call the set of words generated by a grammar the *language generated by the grammar*. The languages generated by algebraic grammars are called *algebraic languages* or *context-free languages*.

5.1.2 Extended algebraic grammars

Extended algebraic grammars are algebraic grammars where the members on the right side of the rule are not just sequences of symbols but regular expressions. Thus, the grammar that generates a sequence of an arbitrary number of a 's can be written as a grammar consisting of one rule:

$$S \rightarrow a^*$$

These grammars, also called *recursive transition networks (RTN)* or *syntax diagrams*, are suited for a user-friendly graphical representation. Indeed, the right member of a rule can be represented as a graph whose name is the left member of the rule.

However, Unitex grammars are not exactly extended algebraic grammars, since they contain the notion of *transduction*. This notion, which is derived from the field of finite state automata, enables a grammar to produce some output. With an eye towards clarity, we will use the terms grammar or graph. When a grammar produces outputs, we will use the term *transducer*, as an extension of the definition of a transducer in the area of finite state automata.

5.2 Editing graphs

5.2.1 Creating a graph

In order to create a graph, click on "New" in the "FSGraph" menu (5.1).

You will then see the window coming up as in figure 5.2.

In order to import Intex graphs into Unitex, you have to convert them into Unicode. The process is the same as for texts (see section 2.2).

The symbol in arrow form is the *initial state* of the graph. The round symbol with a square is the *final state* of the graph. The grammar only recognizes expressions that are described along the paths between initial and final states.

In order to create a box, click inside the window while pressing the Ctrl key. A blue rectangle will appear that symbolizes the empty box that was created (see figure 5.3).

When the box is created, it is automatically selected.

Figure 5.1: FSGraph menu

Figure 5.2: Empty graph

If you use Unitex on a Macintosh device, you must press the "Command key" instead of Ctrl in every action involving the Ctrl key.

You see the contents of the box in the text field at the top of the window (figure 5.3). The newly created box contains the $\langle E \rangle$ symbol that represents the empty word epsilon. Replace this symbol by the text `I+you+he+she+it+we+they` and press the Enter key. You see that the box now contains seven lines (see figure 5.4).

Figure 5.3: Creating a box

Figure 5.4: Box containing I+you+he+she+it+we+they

The + character serves as a separator. The box is displayed in the form of red text lines since it is not connected to another one at the moment. We often use this type of boxes to insert comments into a graph.

If you intend to insert comments into a graph, you can create a box starting with /. The text in this box will be displayed in green, and may contain empty lines. This box can't have any incoming nor outgoing transitions (see figure 5.5).

To connect a box to another one, first click on the source box, then click on the target box. If

Figure 5.5: Box containing comments

there already exists a transition between two boxes, it is deleted. It is also possible to do that by clicking first on the target box and then on the source box while pressing Shift. In our example, after connecting the box to the initial and final states of the graph, we get a graph as in figure 5.6:

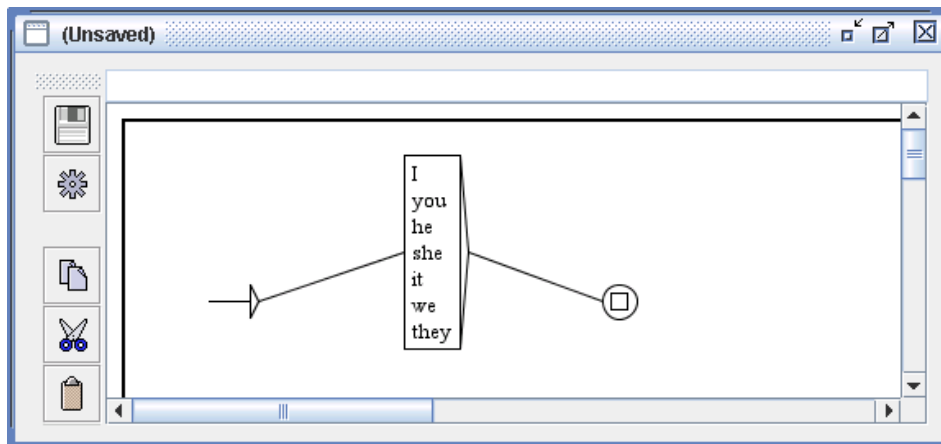

Figure 5.6: Graph that recognizes English pronouns

NOTE: If you double-click a box, you connect this box to itself (see figure 5.7). To undo this double-click on the same box a second time, or use the "Undo" button.

Click on "Save as..." in the "FSGraph" menu to save the graph. By default, Unitex proposes to save the graph in the sub-directory `Graphs` in your working directory. You can

Figure 5.7: Box connected to itself

see if the graph was modified after the last saving by checking if the title contains the text (Unsaved).

Loops are allowed in graphs. They can be around a single box, as in fig. 5.7, or around several boxes, as in fig. 5.17. The content of the loop will be recognized any number of times in sequence. You can set limits to the number of times, but only for a loop around a single box: see section 6.2.4.

When editing a graph you can bring up a specific contextual menu (fig. 5.8) to perform standard graph edition operations by right clicking in the background of the graph window.

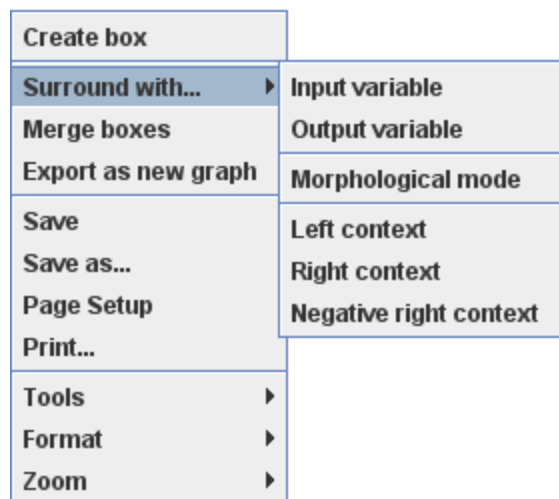

Figure 5.8: contextual menu

This menu will offer several operations that are frequently used when editing a graph.

- create a new box
- save, print the current graph or set up the page parameters
- the usual "Tools", "Format" and "Zoom" menu also accessible in the FSGraph menu

If one or several boxes are currently selected, the following menus will be accessible, allowing you to apply specific operations to these sets of boxes. Otherwise, these menus are useless and therefore non accessible.

- surround selected boxes with an input or output variable definition, with contexts, or with Morphological mode delimiters. These operations are also accessible via the Toolbar of the graph edition window (see section 5.2.8).
- merge selected boxes
- export as a new graph

5.2.2 Sub-Graphs

In order to call a sub-graph, its name is inserted into a box and preceded by the `:` character. If you enter the text:

```
alpha+:beta+gamma+:E:\greek\delta.grf
```

into a box, you get a box similar to the one in figure 5.9:

Figure 5.9: Graph that calls sub-graphs `beta` and `delta`

You can indicate the full name of the graph (`E:\greek\delta.grf`) or simply the base name without the path (`beta`); in this case, the sub-graph is expected to be in the same directory as the graph that references it. References to absolute path names should as a rule be avoided, since such calls are not portable. If you use such an absolute path name, the graph compiler will emit a warning (see figure 5.10).

For portability you should not use `\` or `/` as separator in graph path names. Use instead `:` which is understood as a system-independent separator. In figure 5.10 `\` and `/` are internally converted by the graph compiler to `:` (`E::greek:delta.grf`).

Graph repository

When you need to call a grammar `X` inside a grammar `Y`, a simple method is to copy all the graphs of `X` into the directory that contains the graphs of `Y`. This method raises two problems:

- the number of graphs in the directory grows quickly;
- two graphs cannot share the same name.

Figure 5.10: Warning about a non portable graph name

To avoid that, you can store the grammar X in a special directory, called the *graph repository*. This directory is a kind of library where you can store graphs, and then call them using `::` instead of `.`. To use this mechanism, you first need to set the path to the graph repository. Go into the "Info>Preferences...>Directories" menu, and select your directory in the "Graph repository" frame (see Figure 5.11). There is one graph repository per language, so feel free to share or not the same directory for all the languages you work with.

Let us assume that we have a repository tree as on Figure 5.12. If we want to call the graph named `DET` that is located in sub-directory `Johnson`, we must use the call `::Det:Johnson:DET` (see Figure 5.13¹).

TRICK: If you want to avoid long path names like `::Det:Johnson:DET`, you can create a graph named `DET` and put it the repository root (here `D:\repository\DET.grf`). In this graph, just put a call to `::Det:Johnson:DET`. Then, you can just call `::DET` in your own graphs. This has two advantages: 1) you do not have long path names; 2) you can modify the graphs in your repository with no constraint on your own graphs, because the only graph that will have to be modified is the one located at the repository root.

Calls to sub-graphs are represented in the boxes by grey lines, as in Fig. 5.14, or brown lines in the case of graphs located in the repository, as in Fig. 5.13. If the `.GRF` File of the sub-graph is not found at the path you indicated, Unitex will try to find a `.fst2` file of the same name. If Unitex can't find any of the `.grf` and `.fst2` files, the call to the missing subgraph will

¹To avoid confusion, graph calls that refer to the repository are displayed in brown instead of grey.

Figure 5.11: Setting the path to the graph repository

Figure 5.12: Graph repository example

Figure 5.13: Call to a graph located in the repository

be displayed on a red line. On Windows, you can open a sub-graph by clicking on the grey line while pressing the Alt key. On Linux, the <Alt+Click> combination is intercepted by the system:² in order to open a sub-graph, middle-click on its name, or click on its name by pressing the left and the right mouse buttons simultaneously.

²If you are working on KDE, you can deactivate <Alt+Click> in kcontrol.

Figure 5.14: Missing called sub-graphs appear in red

The list of subgraphs called from the current graph and the graphs in which the current graph is called can be displayed by clicking on the second and third button of the fourth set of buttons in the toolbar command (see Figure 5.15 and Figure 5.25 in section 5.2.8). In these Lists of subgraphs :

- sub-graphs directly called from the current graph appear with their simple filename
- sub-graphs indirectly called from one of the graphs called by the current graph appear with an arrow before their filename.
- sub-graphs that appear in one of the graphs that are called from the current one but that are unplugged and never processed appear in orange
- sub-graphs that are not found (neither .grf nor .fst2) appear in red

5.2.3 Manipulating boxes

You can select several boxes using the mouse. In order to do so, click and drag the mouse without releasing the button. When you release the button, all boxes touched by the selection rectangle will be selected and are displayed in white on a blue background, as shown on Figure 5.17.

You can select several boxes by keeping simultaneously the <CTRL> and <SHIFT> keys pressed and by clicking on every box you want to add to your current selection. This way you can select several boxes without selecting all the boxes located in their area.

When boxes are selected, you can move them by clicking and dragging the cursor without releasing the button. In order to cancel the selection, click on an empty area of the graph. If you click on a box, all the boxes of the selection will be connected to it.

You can perform a copy-paste with several boxes, as in Figure 5.18. Select them and press <Ctrl+C> or click on "Copy" in the "Edit" menu. The selection is now in the Unitex clipboard. You can then paste this selection by pressing <Ctrl+V> or by selecting "Paste" in the "Edit" menu.

NOTE: You can paste a multiple selection into a different graph from the one where you copied it from.

Figure 5.15: Display the list of all called graphs

Figure 5.16: Selecting several boxes

Figure 5.17: Selecting distant boxes

In order to delete boxes, select them, delete the text that they contain (*i.e.* the text presented in the text field above the window) and press the Enter key.

The initial and final states cannot be deleted.

5.2.4 Transducers

A transducer is a graph in which outputs can be associated with boxes. To insert an output, use the special character /. All characters to the right of it will be part of the output. Thus,

Figure 5.18: Copy-Paste of a multiple selection

the text `one+two+three/number` results in a box like in figure 5.19.

Figure 5.19: Example of a transducer

To create an empty box with an output consisting of `number`, type `<E>/number` (example: the rightmost box in Fig. 5.21 is empty and has an output). The output associated with a box is represented in bold text below it.

Weights

You can assign integer weights to the boxes of a transducer. Thus, when a sequence of tokens is matched by several paths with different outputs (ambiguous transducer), only a path with the highest weight will produce an output. After a locate, this will affect the concordance, in which the matched sequences of words will appear only once with the appropriate output (Figure 5.20).

Figure 5.20: weights in graphs

In order to assign weight 1 to a box, insert $\$(1)\$$ in the output of the box, e.g. as in $\langle E \rangle / \$(1)\$$.

The weight of a path is the latest weight found while traversing the path. A weight can be zero, but cannot be less than zero. A path with a weight (even zero) has higher precedence than a path without weight.

With weights, you can define a priority among paths that match the same sequence. You cannot define a priority among embedded matching sequences (cf. section 4.8.1) or among overlapping matching sequences (cf. section 6.7.3).

Weights are valid only within a graph, not in subgraphs or in calling graphs.

5.2.5 Input Variables

It is possible to select parts of a text sequence recognized by a grammar using input variables. To associate an input variable `var1` with parts of a grammar, use either the button with red parentheses in the toolbar above the graph (Section 5.2.8) or the special symbols $\$var1($ (and $\$var1)$. (These symbols define the beginning and the end of the part to be stored. Create two boxes, one containing $\$var1($ (and the other $\$var1)$. These boxes must not contain anything but the variable name preceded by $\$$ and followed by a parenthesis. Then link these boxes to the zone of the grammar to be stored.) The graph in figure 5.21 recognises a sequence of digits before `dollar` or `dollars`. This sequence will be stored in a variable named `var1`.

Figure 5.21: Using the input variable `var1`

Variable names may contain latin letters (without accents), upper or lower case, numbers, or the `_` (underscore) character. Unitex distinguishes between uppercase and lowercase characters.

Once a variable is defined, you can use it in transducer outputs by surrounding its name with `$`. The grammar in figure 5.22 recognizes a date formed by a month and a year, and produces the same date as an output, but in the order year-month.

Figure 5.22: Inverting month and year in a date

If you want to use the character `$` in the output of a box, you have to double it, as shown on figure 5.21.

When a box redefines a variable that had already been defined, the new value overrides the previous one. Thus, if the variable is defined in a loop, the value of the variable just after the loop depends on the last iteration of the loop.

By default, `Locate` and `LocateTfst` consider that variables that have not been defined are empty. You can modify this behavior as shown in section 6.10.2. Moreover, it is possible to test whether a variable has been defined or not, as shown in section 6.7.5.

5.2.6 Copying lists

It can be practical to perform a copy-paste operation on a list of words or expressions from a text editor to a box in a graph. In order to avoid having to copy every term manually, Unitex

provides a mean to copy lists. To use this, select the list in your text editor and copy it using `<Ctrl+C>` or the copy function integrated in your editor. Then create a box in your graph, and press `<Ctrl+V>` or use the "Paste" command in the "Edit" menu to paste it into the box. A window as in Figure 5.23 opens:

Figure 5.23: Selecting a context for copying a list

This window allows you to define the left and right contexts that will automatically be used for each term of the list. By default, these contexts are empty. If you use the contexts `<` and `.V>` with the following list:

eat
sleep
drink
play
read

you will get the box in figure 5.24:

Figure 5.24: Box resulting from copying a list and applying contexts

5.2.7 Special Symbols

The Unitex graph editor interprets the following symbol in a special manner:

" + : / < > # \

Table 5.1 summarizes the meaning of these symbols for U_nitex, as well as the ways to recognize these characters in texts.

Character	Meaning	Escape
"	quotation marks mark sequences that must not be interpreted by U _n itex, and whose case must be taken verbatim	\ "
+	+ separates different lines within the boxes	"+"
:	: introduces a call to a subgraph	": " or \ :
/	/ indicates the start of a transduction within a box	\ /
<	< indicates the start of a pattern or a meta	"<" or \<
>	> indicates the end of a pattern or a meta	">" or \>
#	# prohibits the presence of a space	"#"
\	\ escapes most of the special characters	\\

Table 5.1: Encoding of special characters in the graph editor

5.2.8 Toolbar Commands

The toolbar above a graph contains shortcuts for certain commands and allows you to manipulate boxes of a graph by using some "tools". This toolbar may be moved by clicking on the "rough" zone. It may also be dissociated from the graph and appear in an separate window (see figure 5.25). In this case, closing this window puts the toolbar back at its initial position. Each graph has its own toolbar.

Figure 5.25: Toolbar

The first two icons are shortcuts for saving and compiling the graph. The following five correspond to the Copy, Cut, Paste, Redo and Undo operations.

The following six icons correspond to edit commands for boxes. The first one, a white arrow, corresponds to the boxes' normal edit mode. The next 5 icons correspond to specific tools. In order to use a tool, click on the corresponding icon: the mouse cursor changes its form and mouse clicks are then interpreted in a particular fashion. What follows is a description of these tools, from left to right:

- creating boxes: creates a box at the empty place where the mouse was clicked;
- deleting boxes: deletes the box that you click on;

- connect boxes to another box: using this utility you select one or more boxes and connect it or them to another one. In contrast to the normal mode, the connections are inserted to the box where the mouse button was released on;
- connect boxes to another box in the opposite direction: this utility performs the same operation as the one described above, but connects the boxes to the one clicked on in opposite direction;
- open a sub-graph: opens a sub-graph when you click on a grey line within a box.

In order to change the cursor back to its normal form, the white arrow, right-click on the background of the graph: then, mouse clicks will be interpreted in the normal way again.

The next icon (showing a wrench) is a shortcut to open the window with the graph display options. The following two icons allow you to view lists of graphs that are related to the current graph by a "graph/subgraph" relation :

- The first displays a list of graphs called by the current graph
- The second button shows the list of all the graphs calling the current graph as a sub-graph.

The two green arrows button will refresh the current graph to load the latest version of the current graph. If any graph has its .grf file changed by any operation while displayed in a Unitex window, a window will pop up to warn you and invite you to refresh its window.

The balance button allows you to compare the current graph to another graph or another version of the same graph. This will display a new window (as in Figure 5.26) containing both graphs with colours pointing out the different types of changes between the two graphs: insertion, removal, moves of each state of the graph and change of the content of a state (respectively in green, red, purple and yellow).

The last six buttons are shortcuts to use variables, morphological mode or insert contexts around one or several selected states. These buttons will be clickable only when one or several states are currently selected :

- $()$: input variable (see section 5.2.5)
- $()$: output variable (see section 6.8)
- $\langle \rangle$: morphological mode (see section 6.4)
- $\$*$: left context (see section 6.3)
- $\$[$: right context (see section 6.3)
- $\$!]$: negative right context (see section 6.3)

Figure 5.26: DIFF

5.3 Display options

5.3.1 Sorting the lines of a box

You can sort the content of a box by selecting it and clicking on "Sort Node Label" in the "Tools" submenu of the "FSGraph" menu. This sort operation does not use the `SortTxt` program. It uses a basic sort mechanism that sorts the lines of the box according to the order of the characters in the Unicode encoding.

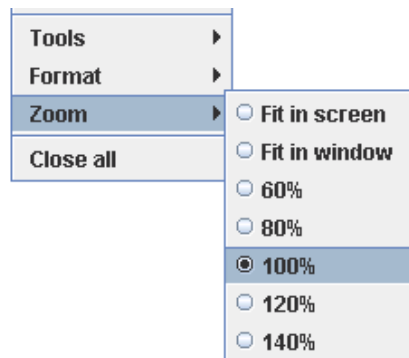

Figure 5.27: Zoom sub-menu

5.3.2 Zoom

The "Zoom" submenu allows you to choose the zoom scale that is applied to display the graph. The "Fit in screen" option stretches or shrinks the graph in order to fit it into the screen. The "Fit in window" option adjusts the graph so that it is displayed entirely in the window.

5.3.3 Antialiasing

Antialiasing is a shading effect that avoids pixelization effects. You can activate this effect by clicking on "Antialiasing..." in the "Format" sub-menu. Figure 5.28 shows one graph displayed normally (the graph on top) and with antialiasing (the graph at the bottom).

Figure 5.28: Antialiasing example

This effect slows Unitex down. We recommend not to use it if your machine is not powerful enough.

5.3.4 Box alignment

In order to get nice-looking graphs, it is useful to align the boxes, both horizontally and vertically. To do this, select the boxes to align and click on "Alignment..." in the "Format" sub-menu of the "FSGraph" menu or press <Ctrl+M>. You will then see the window in Figure 5.29.

The possibilities for horizontal alignment are:

- Top: boxes are aligned with the top-most box;
- Center: boxes are centered on the same axis;
- Bottom: boxes are aligned with the bottom-most box.

Figure 5.29: Alignment window

The possibilities for vertical alignment are:

- Left: boxes are aligned with the left-most box;
- Center: boxes are centered on the same axis;
- Right: boxes are aligned with the right-most box.

Figure 5.30 shows an example of alignment. The group of boxes to the right is (quite) a copy of the ones to the left that was aligned.

The option "Use Grid" in the alignment window shows a grid as the background of the graph. This allows you to approximately align the boxes.

Figure 5.30: Example of box alignment

Figure 5.31: Example of using the grid

5.3.5 Display options, fonts and colors

You can configure the display style of a graph by pressing <Ctrl+R> or by clicking on "Presentation..." in the "Format" sub-menu of the "FSGraph" menu, which opens the window as in figure 5.32.

The font parameters are:

- Input: font used within the boxes and in the text area where the contents of the boxes is edited;
- Output: font used for the attached transducer outputs.

Figure 5.32: Configuring the display options of a graph

The color parameters are:

- Background: the background color;
- Foreground: the color used for the text and for the box display;
- Auxiliary Nodes: the color used for calls to sub-graphs;
- Selected Nodes: the color used for selected boxes;
- Comment Nodes: the color used for boxes that are not connected to others.

The other parameters are:

- Date: display of the current date in the lower left corner of the graph;
- File Name: display of the graph name in the lower left corner of the graph;
- Pathname: display of the graph name along with its complete path in the lower left corner of the graph. This option only has an effect if the option "File Name" is selected;
- Frame: draw a frame around the graph;
- Right to Left: invert the reading direction of the graph (see an example in figure 5.33).

You can reset the parameters to the default ones by clicking on "Default". If you click on "OK", only the current graph will be modified. In order to modify the preferences for a language as a default, click on "Preferences..." in the "Info" menu and click on the "Graph configuration" button in the "Language & Presentation" tab.

Figure 5.33: Graph with reading direction set to right to left

5.4 Exporting graphs

5.4.1 Inserting a graph into a document

In order to include a graph into a document, you have to convert it to an image. To do this, export your graph to an image format: PNG, JPEG or SVG. Click on "Export as image" in the "FSGraph" menu, and select a file format. You will get an image ready to be inserted into a document, or to be edited with an image editor. You should activate antialiasing for the graph that interests you (this is not obligatory but results in a better image quality). Unlike JPEG, PNG uses lossless compression, so PNG always look better than JPEG. Unlike PNG and JPEG, SVG format is not a bitmap format and often look better. Using Inkscape, SVG file can be converted to EPS or PDF with command like:

```
Inkscape -z -E graph.eps graph.svg
```

```
Inkscape -z -A graph.pdf graph.svg
```

Another solution consists of making a screenshot:

On Windows:

Press "Print Screen" on your keyboard. This key should be next to the F12 key. Start the `Paint` program in the Windows "Utilities" menu. Press `<Ctrl+V>`. `Paint` will tell you that the image in the clipboard is too large and asks if you want to enlarge the image. Click on "Yes". You can now edit the screen image. Select the area that interests you. To do so, switch to the select mode by clicking on the dashed rectangle symbol in the upper left corner of

the window. You can now select the area of the image using the mouse. When you have selected the zone, press <Ctrl+C>. Your selection is now in the clipboard, you can now just go to your document and press <Ctrl+V> to paste your image.

On Linux:

Take a screen capture (for example using the program `xv`). Edit your image at once using a graphic editor (for example `TheGimp`), and paste your image in your document in the same way as in Windows.

Vector graphics

If you prefer vector graphics, you can export your graph under the SVG file format, which is editable with softwares like the Open Source one Inkscape ([24]). With this software, you can obtain PostScript exports ready to use in pretty L^AT_EX documents.

5.4.2 Printing a Graph

You can print a graph by clicking on "Print..." in the "FSGraph" menu or by pressing <Ctrl+P>.

WARNING: You should make sure that the page orientation parameter (portrait or landscape) corresponds to the orientation of your graph.

You can setup the printing preferences by clicking on "Page Setup" in the "FSGraph" menu. You can also print all open graphs by clicking on "Print All...".

Chapter 6

Advanced use of graphs

6.1 Types of graphs

Unitex can handle several types of graphs that correspond to the following uses: automatic inflection of dictionaries, preprocessing of texts, normalization of text automata, dictionary graphs, search for patterns, disambiguation and automatic graph generation. These different types of graphs are not interpreted in the same way by Unitex. Certain operations, like transduction, are allowed for some types and forbidden for others. In addition, special symbols are not the same depending on the type of graph. This section presents each type of graph and shows their peculiarities.

6.1.1 Inflection transducers

An inflection transducer describes the morphological variation that is associated with a word class by assigning inflectional codes to each variant. The paths of such a transducer describe the modifications that have to be applied to the canonical forms and the corresponding outputs contain the inflectional information that will be produced.

Figure 6.1: Example of an inflectional grammar

The paths may contain operators and letters. The possible operators are represented by the characters L, R, C, D, U,P and W. All letters that are not operators are characters. The only

allowed special symbol is the empty word `<E>`. It is not possible to refer to information in dictionaries in an inflection transducer, but it is possible to reference subgraphs.

Transducer outputs are concatenated in order to produce a string of characters. This string is then appended to the produced dictionary entry. Outputs with variables do not make sense in an inflection transducer.

Case of letters is respected: lowercase letters stay lowercase, the same for uppercase letters. Besides, the connection of two boxes is exactly equivalent to the concatenation of their contents together with the concatenation of their outputs. (cf. figure 6.2).

Figure 6.2: Two equivalent paths in an inflection grammar

Inflection transducers may be compiled before being used by the inflection program. If not, the inflection program will compile them on the fly.

For more details, see section 3.5.

6.1.2 Preprocessing graphs

Preprocessing graphs are meant to be applied to texts before they are tokenized into lexical units. These graphs can be used for inserting or replacing sequences in the texts. The two customary uses of these graphs are normalization of non-ambiguous forms and sentence boundary recognition.

The interpretation of these graphs in Unitex is very close to that of syntactic graphs used by the search for patterns. The differences are the following:

- you can use the special symbol `<^>` that recognizes a newline;
- if you work in character by character mode, you can use the special symbol `<L>` that recognizes one letter, as defined in the alphabet file;
- it is impossible to refer to information in dictionaries;
- it is impossible to use morphological filters;
- it is impossible to use morphological mode;

- it is impossible to use contexts.

The figures 2.10 (page 34) and 2.11 (page 37) show examples of preprocessing graphs.

6.1.3 Graphs for normalizing the text automaton

Graphs for normalizing the text automaton allow you to normalize ambiguous forms. They can describe several labels for the same form. These labels are then inserted into the text automaton thus making the ambiguity explicit. Figure 6.3 shows an extract of the normalization graph used by default for French.

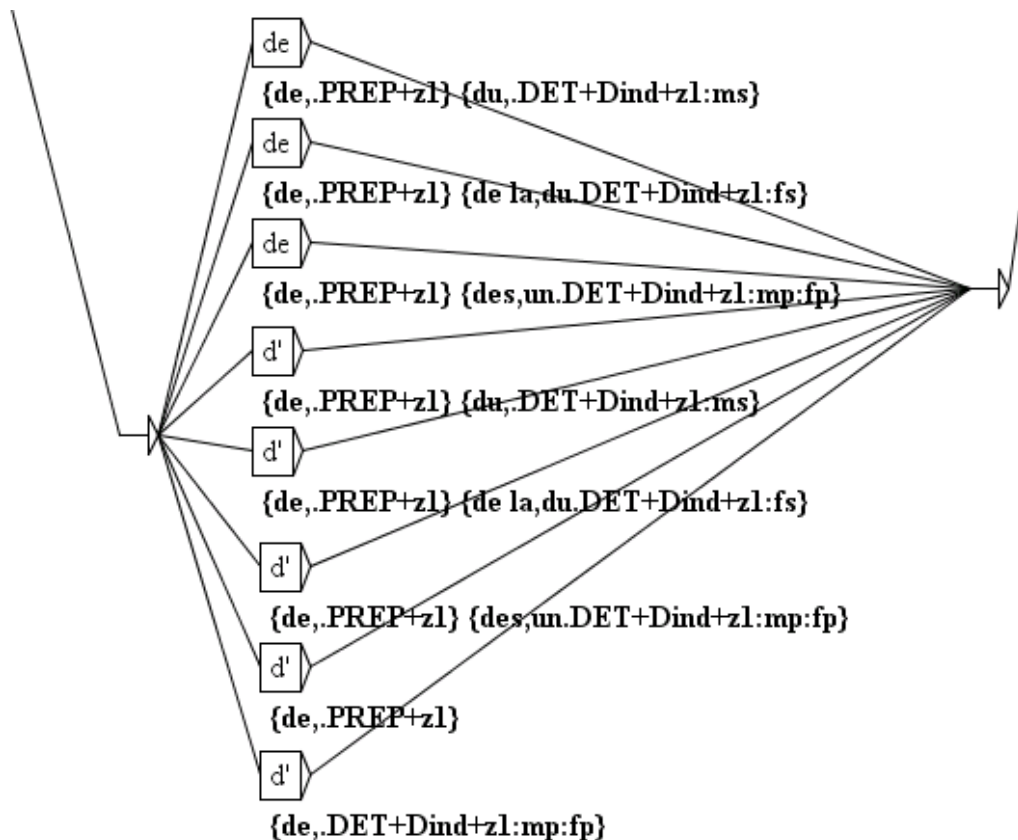

Figure 6.3: Extract of the normalization graph used for French

The paths describe the forms that have to be normalized. Lower case and upper case variants are taken into account according to the following principle: uppercase letters in the graph only recognize uppercase letters in the text automaton; lowercase letters can recognize both lowercase and uppercase letters.

The transducer outputs represent the sequences of labels that will be inserted into the text automaton. These labels can be dictionary entries or strings of characters. The labels that

represent dictionary entries have to respect the DELAF format and must be enclosed by the { and } symbols. Outputs with variables do not make sense in this kind of graph. You cannot use morphological filters, morphological mode or contexts.

It is possible to reference subgraphs. It is not possible to reference information in dictionaries in order to describe the forms to normalize. The only special symbol that is recognized in this type of graph is the empty word <E>. The graphs for normalizing ambiguous forms need to be compiled before using them.

6.1.4 Syntactic graphs

Syntactic graphs, often called local grammars, allow you to describe syntactic patterns that can then be searched in the texts. Of all kinds of graphs these have the greatest expressive power because they allow you to refer to information in dictionaries.

Lower case/upper case variants may be used according to the principle described above. It is still possible to enforce respect of case by enclosing an expression in double quotes. The use of double quotes also allows you to enforce the respect of spaces. In fact, Unitex by default assumes that a space is possible between two boxes. In order to enforce the presence of a space you have to enclose it in double quotes. For prohibiting the presence of a space you have to use the special symbol #.

Syntactic graphs can reference subgraphs (cf. section 5.2.2). They also have outputs including outputs with variables. The produced sequences are interpreted as strings of characters that will be inserted in the concordances or in the text if you want to modify it (cf. section 6.10.4).

Syntactic graphs can use contexts (see section 6.3).

Syntactic graphs can use morphological filters (see section 4.7).

Syntactic graphs can use morphological mode (see section 6.4).

The special symbols that are supported by the syntactic graphs are the same as those that are usable in regular expressions (cf. section 4.3.1).

It is not obligatory to compile syntactic graphs before using them for pattern matching. If a graph is not compiled the system will compile it automatically.

6.1.5 ELAG grammars

ELAG grammars for disambiguation between lexical symbols in text automata are described in section 7.3.1, page 171.

6.1.6 Parameterized graphs

Parameterized graphs are meta-graphs that allow you to generate a family of graphs using a lexicon-grammar table. It is possible to construct parameterized graphs for all possible kinds of graphs. The construction and use of parameterized graphs are explained in chapter 9.

6.2 Compilation of a grammar

6.2.1 Compilation of a graph

Compilation is the operation that converts the `.grf` format to a format that can be manipulated more easily by Unitex programs. In order to compile a graph, you must open it and then click on "Compile FST2" in the "Tools" submenu of the menu "FSGraph". Unitex then launches the `Grf2Fst2` program. You can keep track of its execution in a window (cf. Figure 6.4).

Figure 6.4: Compilation window

If the graph references subgraphs, those are automatically compiled. The result is a `.fst2` file that contains all the graphs that make up a grammar. The grammar is then ready to be used by Unitex programs.

6.2.2 Approximation with a finite state transducer

The FST2 format conserves the architecture in subgraphs of the grammars, which is what makes them different from strict finite state transducers. The `Flatten` program allows

you to turn a FST2 grammar into a finite state transducer whenever this is possible, and to construct an approximation if not. This function thus permits to obtain objects that are easier to manipulate and to which all classical algorithms on automata can be applied.

In order to compile and thus transform a grammar, select the command "Compile & Flatten FST2" in the "Tools" submenu of the "FSGraph" menu. The window of Figure 6.5 allows you to configure the approximation process.

Figure 6.5: Configuration of approximation of a grammar

The box "Flattening depth" lets you specify the level of embedding of subgraphs. This value represents the maximum depth up to which the callings of subgraphs will be replaced by the subgraphs themselves.

The "Expected result grammar format" box allows you to determine the behavior of the program beyond the selected limit. If you select the "Finite State Transducer" option, the calls to subgraphs will be replaced by $\langle \epsilon \rangle$ beyond the maximum depth. This option guarantees that we obtain a finite state transducer, however possibly not equivalent to the original grammar. On the contrary, the "equivalent FST2" option indicates that the program should allow for subgraph calls beyond the limited depth. This option guarantees the strict equivalence of the result with the original grammar but does not necessarily produce a finite state transducer. This option can be used for optimizing certain grammars.

A message indicates at the end of the approximation process if the result is a finite state transducer or an FST2 grammar and in the case of a transducer if it is equivalent to the original grammar (cf. Figure 6.6).

6.2.3 Constraints on grammars

With the exception of inflection grammars, a grammar can never have an empty path. This means that the paths of a main graph must not recognize the empty word but this does not prevent a subgraph of that grammar from recognizing epsilon.

Figure 6.6: Resultat of the approximation of a grammar

It is not possible to associate a transducer output with a call to a subgraph. Such outputs are ignored by Unitex. It is therefore necessary to use an empty box that is situated to the left of the call to the subgraph in order to specify the output (cf. Figure 6.7).

Figure 6.7: How to associate an output with a call to a subgraph

The grammars must not contain void loops because the Unitex programs cannot terminate the exploration of such a grammar. A void loop is a configuration that causes the `Locate`

program to enter an infinite loop. Void loops can originate from transitions that are labeled by the empty word or from recursive calls to subgraphs.

Void loops due to transitions with the empty word can have two origins of which the first is illustrated by the Figure 6.8. This type of loops is due to the fact that a transition with the empty word cannot be eliminated automatically by Unitex because it is associated with an output. Thus, the transition with the empty word of Figure 6.8 will not be suppressed and will cause a void loop.

Figure 6.8: Void loop due to a transition by the empty word with a transduction

The second category of loop by epsilon concerns the call to subgraphs that can recognize the empty word. This case is illustrated in Figure 6.9: if the subgraph `Adj` recognizes epsilon, there is a void loop that Unitex cannot detect.

Figure 6.9: Void loop due to a call to a subgraph that recognizes epsilon

The third possibility of void loops is related to recursive calls to subgraphs. Look at the graphs `Det` and `DetCompose` in figure 6.10.

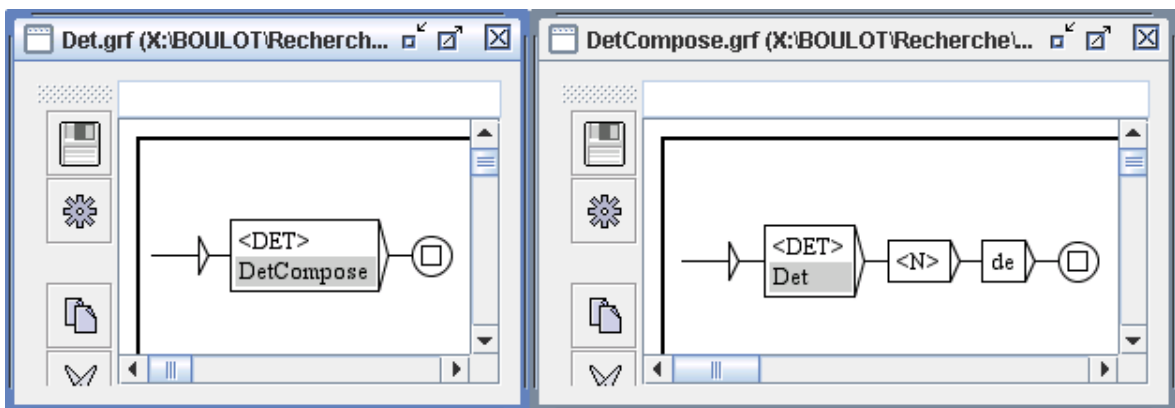

Figure 6.10: Void loop caused by two graphs calling each other

Each of these graphs can call the other *without reading any text*. The fact that none of these two graphs has labels between the initial state and the call to the subgraph is crucial. In fact, if there were at least one label different from epsilon between the beginning of the graph `Det` and the call to `DetCompose`, this would mean that the Unix programs exploring the graph `Det` would have to read the pattern described by that label in the text before calling `DetCompose` recursively. In this case the programs would loop infinitely only if they recognized the pattern an infinite number of times in the text, which is impossible.

6.2.4 Interval for number of repetitions

In order to recognize token sequences in which one pattern appears once, several times in sequence or never, you can attach an integer interval to a box. This sets limits to the number of times the pattern occurs. The pattern must be described in a single box. If you attach the interval $[m, M]$ to a box containing $\langle A \rangle$ (figure 6.11), the path will match sequences with at least m consecutive adjectives and no more than M .

Figure 6.11: Use of an interval to match several consecutive tokens

Intervals are attached by inserting $\$ [m, M] \$$ into the output of the box, just after the character `"/`, and according to the following rules :

- $[m, M]$ = at least m consecutive terms and no more than M
- $[, M]$ = 0 to M
- $[m,]$ = at least m

The box must not be connected to itself with a direct loop. An interval is compatible with an output in the usual sense. For example, to insert `<ADJ position=' anteposed' >` as an output under the box of figure 6.11, type `<A>/\$ [1, 4] \$<ADJ position=' anteposed' >` in the text field.

6.2.5 Error detection

In order to keep the programs from blocking or crashing, Unitex automatically detects errors during graph compilation. The graph compiler checks that the main graph does not recognize the empty word and searches for all possible forms of void loops. When an error is encountered, an error message is displayed in the compilation window. Figure 6.12 shows the message that appears if one tries to compile the graph `Det` of Figure 6.10.

Figure 6.12: Error message when trying to compile `Det`

When you start a pattern search with a `.grf` graph, if Unitex detects an error at the graph compilation, the locate operation is automatically interrupted.

6.3 Contexts

Unitex graphs as we described them up to here are equivalent to algebraic grammars. These are also known as context-free grammars, because if you want to match a sequence A , the context of A is irrelevant. Thus, you cannot use a context-free graph for matching occurrences of `of president` not followed by `of the republic`.

However, you can draw graphs with positive or negative contexts. In that case, graphs are no more equivalent to algebraic grammars, but to context-sensitive grammars that do not have the same theoretical properties.

6.3.1 Right contexts

To define a right context, you must bound a zone of the graph with boxes containing `$ [` and `$]`, which indicate the start and the end of the right context. These bounds appear in the

graph as green square brackets. Both bounds of a right context must be located in the same graph.

Figure 6.13: Using a right context

Figure 6.13 shows a simple right context. The graph matches numbers followed by a currency symbol, but this symbol will not appear in matched sequences, *i.e.* in the concordance.

Right contexts are interpreted as follows. During the application of a grammar on a text, let us assume that a right context start is found. Let *pos* be the current position in the text at this time. Now, the `Locate` program tries to match the expression described inside the right context. If it fails, then there will be no match. If it matches the whole right context (that is to say if `Locate` reaches the right context end), then the program will rewind at position *pos* and go on exploring the grammar after the right context end.

Weights (section 5.2.4) are ignored in right contexts.

You can also define negative right contexts, using `$![` to indicate the right context start. Figure 6.14 shows a graph that matches numbers that are not followed by `th`. The difference with positive right contexts is that when `Locate` tries to match the expression described inside the context, reaching the context stop will be considered as a failure, because it would have matched a forbidden sequence. At the opposite, if the context stop cannot be reached, then `Locate` will rewind at the position *pos* and go on exploring the grammar after the context end.

Figure 6.14: Using a negative right context

Right contexts can appear anywhere in the graph, including the beginning of the graph. Figure 6.15 shows a graph that matches an adjective in the right context of something that is not a past participle. In other words, this graph matches adjectives that are not ambiguous with past participles.

Figure 6.15: Matching an adjective that is not ambiguous with a past participle

Figure 6.16: A context that does not check the same number of words as the box after it

In graphs like that of Figure 6.15, the negative right context does not need to match the same number of tokens as the box after it. For example, before the graph of Figure 6.16 recognizes *too*, the negative right context checks if it occurs in a phrase like *too early* or *too many*.

Negative right contexts allow you to formulate complex patterns. For instance, the graph of figure 6.17 matches a sequence of two simple nouns that is not ambiguous with a compound word. In fact, the pattern `<CDIC><<^[^]+ [^]+>>` matches a compound word with exactly one space, and the pattern `<N><<^[^]+>>` matches a noun without space, that is to say a simple noun. Thus, in the sentence *Black cats should like the town hall*, this graph will match *Black cats*, but not *town hall*, which is a compound word.

Figure 6.17: Advanced use of right contexts

You can use nested contexts. For instance, the graph shown in figure 6.18 matches a number that is not followed by a dot, except for a dot followed by a number. Thus, in the sequence *5.0+7.=12*, this graph will match *5*, *0* and *12*.

If a right context contains boxes with transducer outputs, the outputs are ignored. However, it is possible to use a variable that was defined inside a right context (cf. figure 6.19). If you apply this graph in MERGE mode to the text *the cat is white*, you will obtain:

```
the <pet name="cat" color="white"/> is white
```

Figure 6.18: Nested contexts

Figure 6.19: Variable defined inside a right context

6.3.2 Left contexts

It is also possible to look for an expression X only if it occurs after an expression Y . Of course, it was already possible to do that with a grammar like the one shown on Figure 6.20. However, with such a grammar, the context part on the left will be included in the match, as shown on Figure 6.21.

Figure 6.20: Matching a noun that occurs after a numeral determiner

To avoid that, you can use the special symbol $\$*$ to indicate the end of the left context of the expression you want to match. This symbol will be represented by a green star in the graph, as shown on Figure 6.22. The effect of such a context is to use this part of the grammar for computing matches, but to ignore it in the results, as shown on Figure 6.23.

Figure 6.21: Results of the application of the grammar shown on Figure 6.20

Figure 6.22: Matching a noun after a left context

Figure 6.23: Results of the application of the grammar shown on Figure 6.22

All the outputs produced in the left context are ignored, as you can see in the concordance of Figure 6.25, showing the results obtained with the grammar of Figure 6.24.

Figure 6.24: Ignored output in a left context

Figure 6.25: Results of the application of the grammar shown on Figure 6.24

However, you can store information in variables (see section 6.7.5) and use it outside the left context, as shown on the grammar of Figure 6.26 which produces the concordance of Figure 6.27.

A graph with left contexts may be invoked in a grammar, but this requires caution. When the left context part is excluded from the match, any sequences that had been matched before by any of the calling graphs are excluded from the match too, because the eventual matched sequence must be contiguous. Any outputs in excluded sequences are ignored too.

Thus, with left and right contexts, you can make a distinction between patterns used to match spots in texts, and the delimitation of the sequences to be extracted into your results. For instance, the grammar shown on Figure 6.28 looks for expressions like `the animal's`, but only extracts nouns, as you can see on Figure 6.29.

Weights (section 5.2.4) work normally in left contexts.

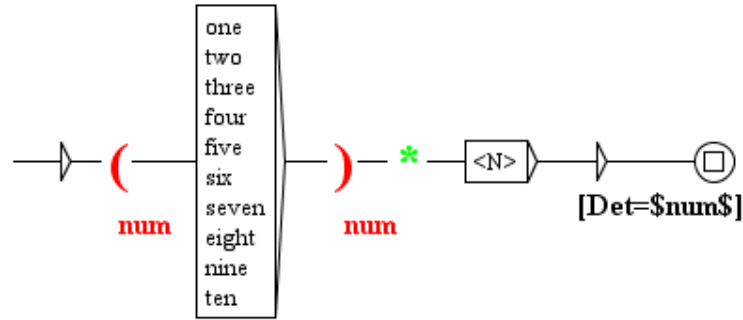

Figure 6.26: Using a variable in a left context

Figure 6.27: Results of the application of the grammar shown on Figure 6.26

Figure 6.28: A grammar with both left and right contexts

Figure 6.29: Results of the application of the grammar shown on Figure 6.28

6.4 The morphological mode

6.4.1 Why?

As Unitex works on a tokenized version of the text, it is not possible to perform queries that need to enter inside tokens, except with morphological filters (see section 4.7), as shown on Figure 6.30.

Figure 6.30: Matching morphological elements

However, even morphological filters cannot allow any query, since they cannot refer to information stored in dictionaries. Thus, it is impossible to formulate this way a query like “a word made of the prefix `un` followed by an adjective suffixed with `able`”.

To overcome this difficulty, we introduced a morphological mode in the `Locate` program. It consists of bounding a part of your grammar with the special symbols `$<` and `$>`. Within this zone, sequences are matched letter by letter, as shown on Figure 6.31.

Figure 6.31: Example of morphological zone in a grammar

6.4.2 The rules

In this mode, the content of the graph is not interpreted as it is in the normal way.

1. There is no implicit space between boxes. So, if you want to match a space, you have to make it explicit with " " (a space between double quotes).
2. You can still use subgraphs, but the end of the morphological zone must occur in the same graph as its beginning.
3. You can use lexical masks involving dictionary lookup—such as `<DIC>`, `<be>` or `<N:ms>`, which refer to information stored in a dictionary—, provided that the dictionary has been previously declared as a morphological-mode dictionary (section 6.4.3).

4. You can use lexical masks involving a lookup in a dictionary graph (section 3.8.3), provided that the name of the dictionary graph contains the `b` switch. However, this feature works only for forms recognized by the dictionary graph in the text during initial application of dictionaries (section 3.8), and not for forms that occur in the text only as token parts.
5. You can use morphological filters (section 4.7). However, morphological filters used alone or on `<TOKEN>` will only apply to the current character. As a consequence, filters like `<<[1-9][0-9]>>` that are meant to match more than one character will never match anything. In fact, in morphological mode, morphological filters should only be used to express negations like `<<[^aeiouy]>>` (any character that is not a vowel).
6. Left and right contexts are forbidden.
7. You can use outputs.
8. `<LETTER>` will match any letter, as defined in the alphabet file.
9. `<LOWER>` will match any lowercase letter, as defined in the alphabet file.
10. `<UPPER>` will match any uppercase letter, as defined in the alphabet file.
11. `<DIC>` will match any word present in a morphological-mode dictionary, but the meta-symbols `#`, `<FIRST>`, `<NB>`, `<SDIC>` and `<CDIC>` are forbidden.
12. If you reach the end of the morphological zone and if you are not at the end of a token, the match will fail. For instance, if the text contains `enabled`, you cannot match `enable` only.

Earlier codes for `<LETTER>`, `<LOWER>` and `<UPPER>` were respectively `<MOT>`, `<MIN>` and `<MAJ>`. They can still be used for backward compatibility of the system with existing graphs. Though there are no current plans to remove this codes, it is recommended to avoid them in graphs designed to be used with more recent versions,¹ so that the number of lexical masks in use does not increase uselessly.

6.4.3 Morphological-mode dictionaries

In morphological mode, you can perform queries using dictionaries. For instance, the grammar of Figure 6.32 searches for every word made of the prefix `un` followed by an adjective.

Figure 6.32: Matching words made of 'un'+adjective ending with 'able'

¹From version 3.1beta, revision 4072, October 2, 2015.

Figure 6.33: Configuration of morphological-mode dictionaries

To be able to match with this grammar the word *unaware*, the system must know that *aware* is an adjective. The lexical mask `<A>` involves a dictionary lookup. But *aware* may not be present in the text, so that we cannot rely on the text dictionaries.² This is the reason why we must define a list of dictionaries to be looked up in the morphological mode. To do that, go in “Info>Preferences>Morphological-mode dictionaries”, as shown on Figure 6.33. You can select as many dictionaries as you want, but they MUST be `.bin` ones. Once this is done, you can apply your grammar and get results. In order to specify that a dictionary-graph should be looked up in the morphological mode, use option `b` or `z` (section 3.8.3, Exporting produced entries as a morphological-mode dictionary).

6.4.4 Dictionary-entry variables

You can set variables to information stored in morphological-mode dictionaries. The initialization of such a variable must be associated to a box that contains a pattern referring to information stored in a morphological-mode dictionary, except for the pattern `<DIC>`. Set the output of the box with `xxx` where `xxx` is a valid variable name (cf. section 5.2.5). That sets a special variable named `xxx` to the dictionary entry that matches with your pattern. In the rest of the paths that contain the box, you can get the inflected form, lemma and codes of the entry with `$xxx.INFLECTED$`, `$xxx.LEMMA$` and `$xxx.CODE$`, as shown on Figure 6.34. You can also use the following patterns:

- `$xxx.CODE.GRAM$`: provides only the first grammatical code, supposed to be the POS category
- `$xxx.CODE.SEM$`: provides all remaining grammatical codes, if any, separated with `+`

²The text dictionaries are compiled during initial application of dictionaries (section 3.8), not during search for patterns.

- `$xxx.CODE.FLEX$`: provides all inflectional codes, if any, separated with `:`
- `$xxx.CODE.ATTR=yyy$`: provides the value of an attribute-value pair contained in the semantic codes, i.e. the value `zzz` of the `yyy` attribute if there is a code of the form `yyy=zzz`.

Dictionary-entry variables can be used even after the end of the morphological mode, as shown on Figure 6.36. They can also be tested as explained in section 6.7.5.

Figure 6.34: Using a dictionary-entry variable

Figure 6.35: Results of grammar of Figure 6.34 applied in MERGE mode

Figure 6.36: Using a dictionary-entry variable in normal mode

Dictionary-entry variables in LocateTfst

In grammars to be applied with `LocateTfst` (cf. section 7.7), you have an extra feature. If you are not in morphological mode, your grammar can extract information from a lexical tag contained in the text automaton, and capture it into a dictionary-entry variable. In your grammar, you have to set the output of a box with `$:xxx$`, where `xxx` is a valid variable name. In the rest of the paths that contain the box, you can use `xxx` as a dictionary-entry variable, in the same way as described above for the morphological mode: you can get from this variable the inflected form, lemma and codes of the entry, its POS code, semantic

codes, inflectional codes and the value *zzz* of the *yyy* attribute if there is a code of the form *yyy=zzz*.

6.5 Exploring grammar paths

It is possible to generate the paths recognized by a grammar, if they are in finite number, for example to check that it correctly generates the expected forms. For that, open the main graph of your grammar, and ensure that the graph window is the active window (the active window has a blue title bar, while the inactive windows have a gray title bar). Now go to the "FSGraph" menu and then to the "Tools" menu, and click on "Explore Graph paths". The Window of figure 6.37 appears.

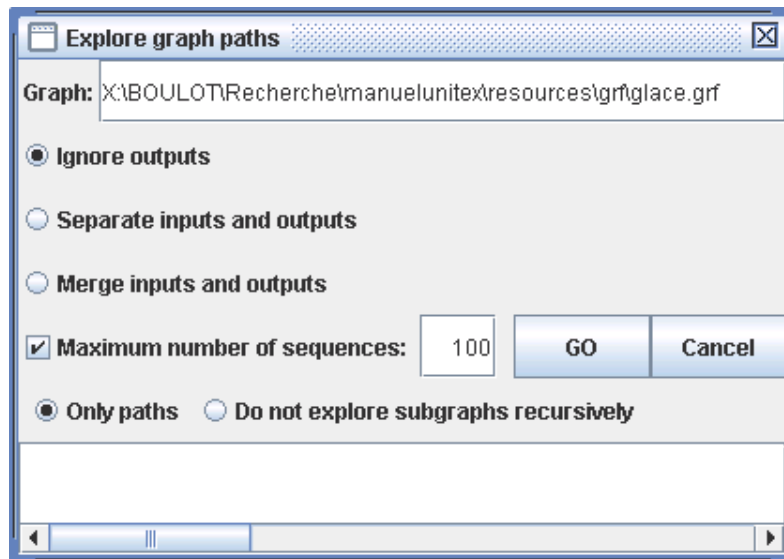

Figure 6.37: Exploring the paths of a grammar

The upper box contains the name of the main graph of the grammar to be explored. The following options are connected to the outputs of the grammar and to subgraph calls:

- "Ignore outputs": outputs are ignored;
- "Separate inputs and outputs": outputs are displayed after inputs (*a b c / A B C*);
- "Merge inputs and outputs": each output is emitted immediately after the input to which it corresponds (*a/A b/B c/C*).
- "Only paths": calls to subgraphs are explored recursively;
- "Do not explore subgraphs recursively": calls to subgraphs are printed but not explored recursively.

If the option "Maximum number of sequences" is activated, the specified number will be the maximum number of generated paths. If the option is not selected, all paths will be generated, if they are in finite number.

Here you see what is created for the graph shown on Figure 6.38 with default settings (ignoring outputs, limit = 100 paths):

```
<NB> <boule> de glace à la pistache
<NB> <boule> de glace à la fraise
<NB> <boule> de glace à la vanille
<NB> <boule> de glace vanille
<NB> <boule> de glace fraise
<NB> <boule> de glace pistache
<NB> <boule> de pistache
<NB> <boule> de fraise
<NB> <boule> de vanille
glace à la pistache
glace à la fraise
glace à la vanille
glace vanille
glace fraise
glace pistache
```

Figure 6.38: Sample graph

6.6 Graph collections

It can happen that one wants to apply several grammars located in the same directory. For that, it is possible to automatically build a grammar starting from a file tree structure. Let us suppose for example that one has the following tree structure:

- *Dicos*:
 - *Banque*:
 - * *carte.grf*
 - *Nourriture*:

```

* eau.grf
* pain.grf
- truc.grf

```

If one wants to gather all these grammars in only one, one can do it with the "Build Graph Collection" command in the "FSGraph Tools" sub-menu. One configures this operation by means of the window seen in figure 6.39.

Figure 6.39: Building a graph collection

In the "Source Directory" field, select the root directory which you want to explore (in our example, the directory *Dicos*). In the field "Resulting GRF grammar", enter the name of the produced grammar.

WARNING: Do not place the output grammar in the tree structure which you want to explore, because in this case the program will try to read and to write simultaneously in this file, which will cause a crash.

When you click on "OK", the program will copy the graphs to the directory of the output grammar, and will create subgraphs corresponding to the various sub-directories, as one can see in figure 6.40, which shows the output graph generated for our example.

One can observe that one box contains the calls with subgraphs corresponding to sub-directories (here directories *Banque* and *Nourriture*), and that the other box calls all the graphs which were in the directory (here the graph `truc.grf`).

6.7 Rules for applying transducers

This section describes the rules for the application of transducers along with the operations of preprocessing and the search for patterns. The following does not apply to inflection graphs and normalization graphs for ambiguous forms.

Figure 6.40: Main graph of a graph collection

6.7.1 Insertion to the left of the matched pattern

When a transducer is applied in REPLACE mode, the output replaces the sequences that have been read in the text. When a box in a transducer has no output, it is processed as if it had an <E> output. In MERGE mode, the output is inserted to the left of the recognized sequences.

Figure 6.41: Example of a transducer

Look at the transducer in Figure 6.41. If this transducer is applied to the novel *Ivanhoe* by Sir Walter Scott in MERGE mode, the following concordance is obtained.

6.7.2 Application while advancing through the text

During the preprocessing operations, the text is modified as it is being read. In order to avoid the risk of infinite loops, it is necessary that the sequences that are produced by a transducer will not be re-analyzed by the same one. Therefore, whenever a sequence is inserted into the text, the application of the transducer is continued after that sequence. This rule only applies to preprocessing transducers, because during the application of syntactic graphs, the transductions do not modify the processed text but a concordance file which is distinct from the text.

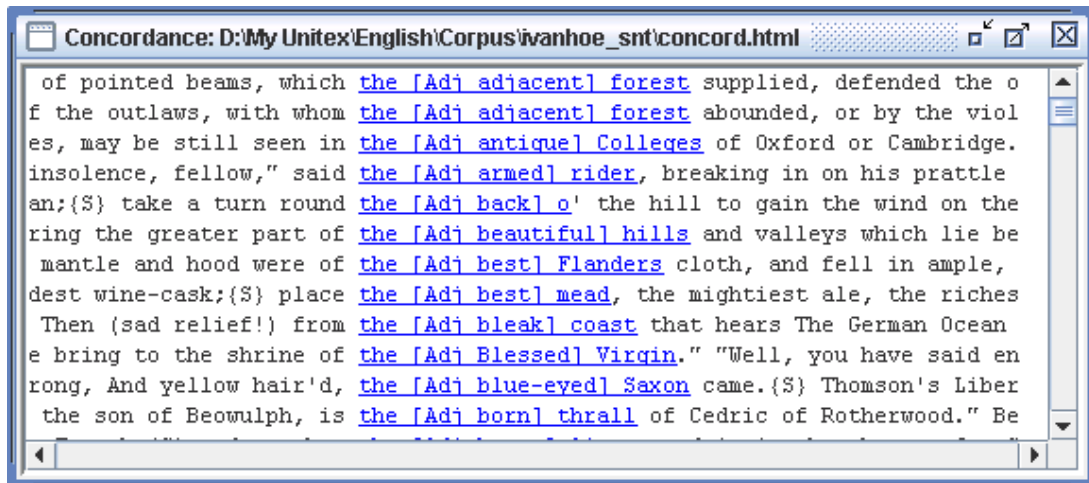

Figure 6.42: Concordance obtained in MERGE mode with the transducer of figure 6.41

6.7.3 Priority of the leftmost match

During the application of a local grammar, overlapping occurrences are all indexed. Note that we talk about real overlapping occurrences like *abc* and *bcd*, not nested occurrences like *abc* and *bc*. During the construction of the concordance all these overlapping occurrences are presented (cf. Figure 6.43).

```

iver Don, there extended [in ancient] times a large forest, covering the gr
r Don, there extended in [ancient times] a large forest, covering the great
here extended in ancient [times a] large forest, covering the greater part

```

Figure 6.43: Overlapping occurrences in concordance

On the other hand, if you modify a text instead of constructing a concordance, it is necessary to choose among these occurrences the one that will be taken into account. Unitex applies the following priority rule for that purpose: the leftmost sequence is used.

If this rule is applied to the three occurrences of the preceding concordance, the occurrence *[in ancient]* overlaps with *[ancient times]*. The first is retained because this is the leftmost occurrence and *[ancient times]* is eliminated. The following occurrence of *[times a]* is no longer in conflict with *[ancient times]* and can therefore appear in the result:

```

...Don, there extended [in ancient] [times a] large forest...

```

The rule of priority of the leftmost match is applied only when the text is modified, be it during preprocessing or after the application of a syntactic graph (cf. section 6.10.4).

6.7.4 Priority of the longest match

During the application of a syntactic graph it is possible to choose if the priority should be given to the shortest or the longest sequences or if all sequences should be retained. During preprocessing, the priority is always given to the longest sequences.

6.7.5 Transducer outputs with variables

As we have seen in Section 5.2.5, it is possible to use input variables to store some text that has been analyzed by a grammar. Such variables can be used in preprocessing graphs and in syntactic graphs.

Figure 6.44: Definition of an input variable in a subgraph

You have to give names to the variables you use. These names can contain non-accented lower-case and upper-case letters between A and Z, digits and the character _ (underscore).

In order to delimit the zone to be stored in an input variable, either use the button with red parentheses in the toolbar above the graph (Section 5.2.8) or create two boxes, one containing

the name of the variable enclosed in the characters \$ and (for the beginning of the zone and the other in \$ and) for the end. In order to use a variable in a transducer output, its name must be surrounded by the character \$ (cf. Figure 6.44).

Variables are global. This means that you can define a variable in a graph and reference it in another as is illustrated in the graphs of Figure 6.44. If the graph `TitleName` is applied in MERGE mode to the text *Ivanhoe*, the concordance in Figure 6.45 is obtained.

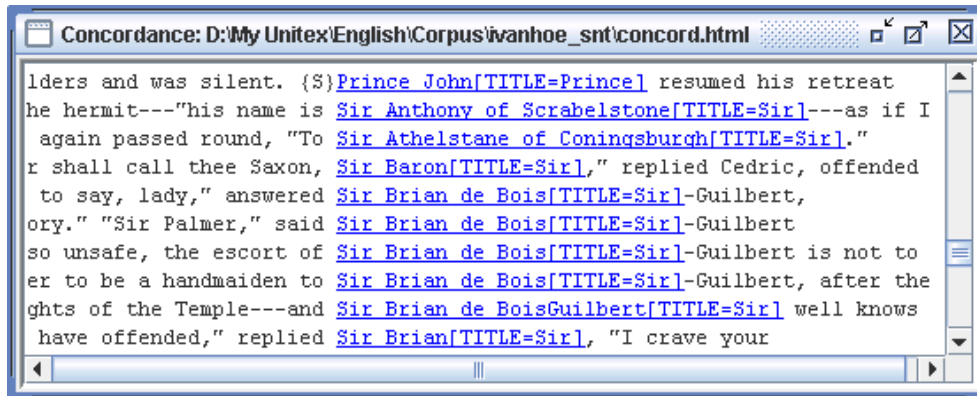

Figure 6.45: Concordance obtained by application of graph `TitleName` of Fig. 6.44

Outputs with variables can be used to move phrases. In fact, the application of a transducer in REPLACE mode inserts only the produced sequences into the text. In order to swap two phrases, you just have to store them into variables and produce an output with these variables in the desired order. Thus, the application of the transducer in Figure 6.46 in REPLACE mode to the text *Ivanhoe* results in the concordance of Figure 6.47.

Figure 6.46: Swapping words using two input variables

If the beginning or the end of variable does not conform to the syntax above (end of a variable before its beginning, or absence of the beginning or end of a variable), by default, it will be ignored during the emission of outputs. See section 6.10.2 for other variable error policies.

There is no limit to the number of possible variables.

Input variables can be nested and even overlap as is shown in figure 6.48.

Figure 6.47: Result of the application of the transducer in figure 6.46

Figure 6.48: Overlapping input variables

6.8 Output variables

Input variables declared either with the red-parentheses button or with $\$xxx$ (and $\$xxx$) capture portions of the input text. It is also possible to capture portions of the outputs produced by your grammar. This is done with output variables. Such variables are declared either with the button with blue parentheses in the toolbar above the graph (Section 5.2.8) or with $\$|xxx$ (and $\$|xxx$). The resulting boxes appear in blue as shown on Figure 6.49. This example grammar applied to *Ivanhoe* will produce in MERGE mode the concordance shown on Figure 6.50.

Figure 6.49: Output variables

Figure 6.50: Concordance obtained with grammar of Figure 6.49

When an output variable is being initialized, the output sequences of the transducer are not emitted into the output for the current occurrence; they are just stored into the pending output variable(s). For instance, the outputs ADJ and NOUN of Figure 6.49 have not been inserted to the left of the input text on Figure 6.50. Outputs are processed before being stored, so that if an output string contains something like $\$A.LEMMA\$,$ the output variable will actually not contain this raw string but the lemma associated to variable A.

Output variables only capture explicit outputs produced by your grammar. Thus, even in MERGE mode, output variables never capture the input text (Figures 6.49 and 6.50).

When a box redefines a variable that had already been defined, the new value overrides the

previous one. Thus, if the variable is defined in a loop, the value of the variable just after the loop depends on the last iteration of the loop.

6.9 Operations on variables

6.9.1 Testing variables

It is possible to test whether a variable has been defined or not, in order to block the current matching operation if the condition is not verified. This is done by inserting the sequence `$xxx.SET$` in the output of a graph box. Then, if a variable named `xxx` has been defined, this sequence will be ignored in the output and the matching process will go on; otherwise, matching will be stopped and the program will backtrack. This operates on input variables as well as on output variables and dictionary-entry variables defined in morphological mode. You can check out if a variable has not been defined in the same way using `$xxx.UNSET$`. Figure 6.51 shows a graph that use a such a variable test. Figure 6.52 shows results obtained with this graph in MERGE mode.

Figure 6.51: Testing a variable

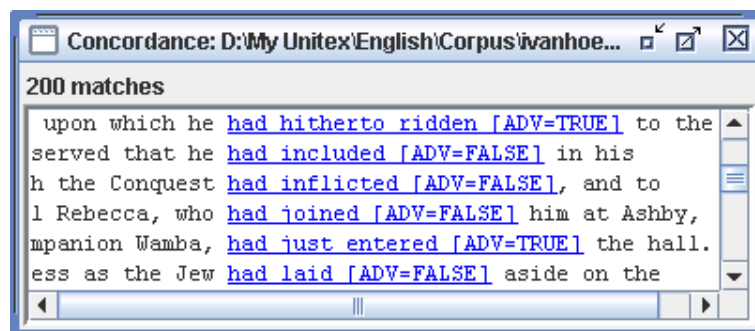

Figure 6.52: Results of a variable test

6.9.2 Comparing variables

Another kind of test you can perform consists of variable comparison. You can compare a variable of any kind (whether an input variable, an output variable or a dictionary-entry variable) against a constant string or another variable. To do that, insert in the output of a graph box a sequence with the following syntax:

```
$abc.EQUAL=xyz$
```

This test acts like a switch that will block the grammar exploration if the value of variable `abc` is different from the value of variable `xyz`. Note that for dictionary-entry variables, what is used in the test is the inflected form as found in the dictionary (beware of case variations!). If you want to compare variable `abc` against the constant string `JKL`, use the following test:

```
$abc.EQUAL=#JKL$
```

You can also test if contents differ with `UNEQUAL`.

If you want to compare variables so that case variations are ignored, you can use the following tests:

```
$abc.EQUALcC=xyz$
```

or

```
$abc.UNEQUALcC=xyz$
```

6.9.3 Querying variables

You can search a dictionary-entry variable (section 6.4.4) for a ‘semantic code’ (in the sense of section 3.1.1). To do that, insert in the output of a graph box a sequence with the following syntax:

```
$abc.EQ=Conc$
```

This test acts like a switch that will block the grammar exploration if `Conc` is not found among the ‘semantic codes’ of the dictionary-entry variable `abc`. You can search a variable for one code at a time. To check several codes, chain several boxes.

This feature is used in large sets of morphological dictionary-graphs in order to dissociate in distinct boxes a check for a grammatical code and subsequent checks for semantic codes, as in [79], page 486. The grammatical code is checked with the aid of a lexical mask, and the semantic codes are checked by searching the corresponding dictionary-entry variable. Such dissociation may speed up the application of the graphs if:

- all the graphs are directly or indirectly invoked from a single main graph,
- the main graph is compiled and flattened (see section 6.2.2),

- the box with the lexical mask is common to more paths than the boxes searching the dictionary-entry variable for the semantic codes.³

6.10 Applying graphs to texts

This section only applies to syntactic graphs.

6.10.1 Configuration of the search

In order to apply a graph to a text, you open the text, then click on "Locate Pattern..." in the "Text" menu, or press <Ctrl+L>. You can then configure your search in the window shown in figure 6.53.

In the "Locate pattern in the form of" field, choose "Graph" and select your graph by clicking on the "Set" button. You can choose a graph in `.grf` format (Unicode Graphs) or a compiled graph in `.fst2` format (Unicode Compiled Graphs). If your graph is a `.grf` one, Unitex will compile it automatically before starting the search. If you click on "Activate debug mode", the concordance will be displayed in a window in which you will also find the automaton and, for each match, the list of states of the path that matches it. This window is described with more details in section 6.10.7.

The "Index" field allows to select the recognition mode.

- "Shortest matches" : give precedence to the shortest matches;
- "Longest matches" : give precedence to the longest sequences. This is the default mode;
- "All matches" : give out all recognized sequences.

The "Search limitation" field allows you to limit the search to a certain number of occurrences. By default, the search is limited to the 200 first occurrences.

The "Grammar outputs" field concerns transducers. The "Merge with input text" mode allows you to insert the output sequences in input sequences. The "Replace recognized sequences" mode allows you to replace the recognized sequences with the produced sequences. The third mode ignores all outputs. This latter mode is used by default.

In the "Search algorithm" frame, you can specify whether you want to perform the locate operation on the text using the Locate program or on the text automaton with LocateTfst. By default, search is done with the Locate program, as Unitex always did until now. If

³Thus, the lexical mask provokes a search in morphological-mode dictionaries which is performed once before several searches for semantic codes. If you check the grammatical code and a semantic code by the same lexical mask, these masks are more numerous in the complete grammar and they provoke more searches in morphological-mode dictionaries.

Figure 6.53: Locate pattern Window

you want to use `LocateTfst`, please read dedicated section 7.7. After you have selected the parameters, click on "SEARCH" to start the search.

6.10.2 Advanced search options

If you select the "Advanced options" tab, you will see the frame shown on Figure 6.54.

Figure 6.54: Advanced search options

The "Ambiguous output policy" option can be illustrated with the graph shown on Figure 6.55.

Figure 6.55: A graph with ambiguous outputs

When a determiner is followed by a word that can be either adjective or noun, it can produce

two distinct outputs for the same text input sequence (the transducer is said to be ambiguous). If we apply this graph on *Ivanhoe* with the "Allow ambiguous outputs" option (the default one), we will obtain the text order concordance shown of Figure 6.56. As you can see, two outputs have been produced for the input sequence *the noble*.

Figure 6.56: Ambiguous outputs for *the noble*

At the opposite, with the "Forbid ambiguous outputs" option, we will obtain the text order concordance shown of Figure 6.57, with only one arbitrarily chosen output for the input sequence *the noble*.

Figure 6.57: Single output for *the noble*

The "Variable error policy" option allows you to specify what `Locate/LocateTfst` is supposed to do when an output is found that contains a reference to a variable that has not been correctly defined. Note that this parameter has no effect if outputs are to be ignored. For instance, let us consider the graph shown on Figure 6.58.

Figure 6.58: A variable *A* that may be undefined

With the "Ignore variable errors" option, *A* will just be ignored, as if it had an empty content, as shown on Figure 6.59.

Figure 6.59: variable *A* that may be undefined

With the "Exit on variable error" option, `Locate/LocateTfst` will exit with an error message, as shown on Figure 6.60.

With the "Backtrack on variable error" option, `Locate/LocateTfst` will stop exploring the current path in the grammar. Thus, variables play the role of switches that cut paths when variables are undefined. For instance, the application of grammar 6.58 will only produce matches containing an adjective, as shown on Figure 6.61.

Figure 6.60: Exiting on variable error

Figure 6.61: Backtracking on variable error

6.10.3 Concordance

The result of a search is an index file that contains the positions of all encountered occurrences. The window of Figure 6.62 lets you choose whether to construct a concordance or modify the text.

In order to display a concordance, you have to click on the "Build concordance" button. You can parameterize the size of left and right contexts in characters. You can also choose the sorting mode that will be applied to the lines of the concordance in the "Sort According to" menu. For further details on the parameters of concordance construction, refer to section 4.8.2. The concordance is produced in the form of an HTML file. You can parameterize Unitex so that concordance files can be read using a web browser (cf. section 4.8.2).

If you display concordances with the window provided by Unitex, you can access a recognized sequence in the text by clicking on the occurrence. If the text window is not iconified and the text is not too long to be displayed, you see the selected sequence appear (cf. Figure 6.63).

Furthermore, if the text automaton has been constructed, and if the corresponding window

Figure 6.62: Configuration for displaying the encountered occurrences

is not iconified, clicking on an occurrence selects the automaton of the sentence that contains this occurrence.

6.10.4 Modification of the text

You can choose to modify the text instead of constructing a concordance. In order to do that, type a file name in the "Modify text" field in the window of Figure 6.62. This file has to have the extension `.txt`.

If you want to modify the current text, you have to choose the corresponding `.txt` file. If you choose another file name, the current text will not be affected. Click on the "GO" button to start the modification of the text. The precedence rules that are applied during these operations are described in section 6.7.

After this operation, the resulting file is a copy of the text in which transducer outputs have been taken into account. Normalization operations and splitting into lexical units are auto-

Figure 6.63: Selection of an occurrence in the text

matically applied to this text file. The existing text dictionaries are not modified. Thus, if you have chosen to modify the current text, the modifications will be effective immediately. You can then start new searches on the text.

WARNING: if you have chosen to apply your graph ignoring the transducer outputs, all occurrences will be erased from the text.

6.10.5 Extracting occurrences

To extract from a text all sentences containing matches, set the name of your output text file using the "Set File" button in the "Extract units" frame (Figure 6.62). Then, click on "Extract matching units". At the opposite, if you click on "Extract unmatching units", all sentences that do not contain any match will be extracted.

6.10.6 Comparing concordances

With the "Show differences with previous concordance" option, you can compare the current concordance with the previous one. The `ConcorDiff` program builds both concordances according to text order and compares them line by line. The result is an HTML page that presents alternatively lines from both concordances, leaving an empty line when a match appears in only one concordance. Lines are greyed for the previous concordance and left with a white background for the current one. In each line, only matched tokens are coloured. You can click on each match to open the text at its position. Figure 6.64 gives an example.

Blue indicates that an occurrence is common to the two concordances. Red indicates that a match is common but with a different range, i.e. the two matches only overlap partially. Green indicates an occurrence that appears in only one concordance.

Figure 6.64: Example of a concordance comparison

If you have no previous concordance the button is deactivated.

6.10.7 Debug mode

When you apply a graph to a text with the Locate menu in the window shown in figure 6.53, if you activate the debug mode in the "Locate pattern in the form of" field, the concordance will be displayed in a special window such as in figure 6.65, divided into three parts :

In the top right part of the window is the concordance. It is identical to the classical concordance in which the sequences matched by the graph appear in blue.

In the bottom right you will find the graph used for the search.

In the left side of the window is a table of 3 columns : "Tag", "output" and "matched". Each token of the matched sequence appear in the "matched" column, the Tag column contains what is in the box of the automaton that matched it, and if this box has any output, it will appear in the "output" column.

For each matched sequence in the concordance, if you click on its line in the concordance, the table on the left will be actualized and clicking on a row of the table will colour the corresponding box in the graph. This will help you to see, for each occurrence of a matched

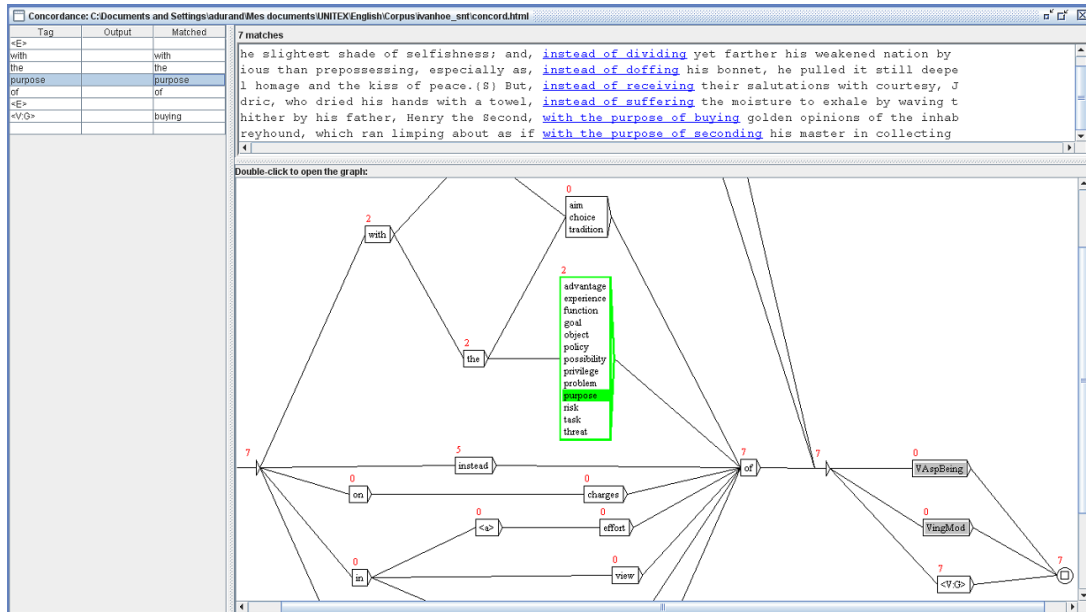

Figure 6.65: The Concordance window in debug mode

sequence in the text, which path in the automaton recognized it. A red number above each box indicates the number of sequences in the text in which that box matched a token.

When you apply a graph in debug mode through the Text > Locate Pattern menu, the system compiles it into a `fst2` file in a special debug-mode format, which is not supported by CasSys. See section 12.2.1 to solve this problem.

Chapter 7

Text automaton

Natural languages contain much lexical ambiguity. The text automaton is an effective and visual way of representing such ambiguity. Each sentence of a text is represented by an automaton whose paths represent all possible interpretations.

This chapter presents the concept of text automaton, the details of their construction and the operations that can be applied, in particular ambiguity removal and linearization. Since version 2.1, it is possible to search the text automaton for patterns (see section 7.7).

7.1 Displaying text automaton

The text automaton explicit all possible lexical interpretations of the words. These different interpretations are the different entries presented in the dictionary of the text. Figure 7.1 shows the automaton of the fourth sentence of the text *Ivanhoe*.

You can see in Figure 7.1 that the word `Here` has three interpretations here (adjective, adverb and noun), `haunted` two (adjective and verb), etc. All the possible combinations are expressed because each interpretation of each word is connected to all the interpretations of the following and preceding words.

In case of an overlap between a compound word and a sequence of simple words, the automaton contains a path that is labeled by the compound word, parallel to the paths that express the combinations of simple words. This is illustrated in Figure 7.2, where the compound word `courts of law` overlaps with a combination of simple words.

By construction, the text automaton does not contain any loop. One says that the text automaton is *acyclic*.

NOTE: The term “text automaton” is an abuse of language. In fact, there is an automaton for each sentence of the text. Therefore, the combination of all these automata corresponds to the automaton of the text. This is why we use the term “text automaton” even if this object is not manipulated as a global automaton for practical reasons.

Figure 7.1: Sentence automaton example

Figure 7.2: Overlap between a compound word and a combination of simple words.

7.2 Construction

In order to construct the text automaton, open the text, then click on "Construct FST-Text..." in the menu "Text". One should first split the text into sentences and apply dictionaries. If sentence boundary detection is not applied, the construction program will arbitrarily split the text in sequences of 2000 lexical units instead of constructing one automaton per sentence. If no dictionaries are applied, the text automaton that you obtain will consist of only one path made up of unknown words per sentence.

7.2.1 Construction rules for text automata

Sentence automata are constructed from text dictionaries. The resulting degree of ambiguity is therefore directly linked to the granularity of the descriptions of dictionaries. From the sentence automaton in figure 7.3, you can conclude that the word *which* has been coded twice as a determiner in two subcategories of the category *DET*. This granularity of descriptions will not be of any use if you are only interested in the grammatical category of this word. It is therefore necessary to adapt the granularity of the dictionaries to the intended use.

Figure 7.3: Double entry for *which* as a determiner

For each lexical unit of the sentence, Unitex searches the dictionary of the simple words of the text for all possible interpretations. Afterwards, all combination of lexical units that have an interpretation in the dictionary of the compound words of the text are taken into account. All the combinations of these information constitute the sentence automaton.

NOTE: If the text contains lexical labels (e.g. {out of date, .A+z1}), these labels are reproduced identically in the automaton without trying to decompose them.

In each box, the first line contains the inflected form found in the text, and the second line contains the canonical form if it is different. The other information is coded below the box. (cf. section 7.5.1).

The spaces that separate the lexical units are not copied into the automaton except for the spaces inside compound words.

The case of lexical units is retained. For example, if the word `Here` is encountered, the capital letter is preserved (cf. figure 7.1). This choice allows you to keep this information during the transition to the text automaton, which could be useful for applications where case is important as for recognition of proper names.

7.2.2 Normalization of ambiguous forms

During the construction of the automaton, it is possible to normalize ambiguous forms by applying a normalization grammar. This grammar has to be called `Norm.fst2` and must be placed in your working directory, in the subdirectory `/Graphs/Normalization` of the language. Normalization grammars for ambiguous forms are described in section 6.1.3.

If a sequence of the text is recognized by the normalization grammar, all the interpretations that are described by the grammar are inserted into the text automaton. Figure 7.4 shows the part of the grammar used for the ambiguity of the sequence `l'` in French.

Figure 7.4: Normalization of the sequence `l'`

If this grammar is applied to a French sentence containing the sequence `l'`, a sentence automaton that is similar to the one in figure 7.5 is obtained.

You can see that the four rules for rewriting the sequence `l'` have been applied, which has added four labels to the automaton. These labels are not concurrent with the two preexisting paths for the sequence `l'`, because of the "keep best paths" heuristic (see section 7.2.4). The normalization at the time of the construction of the automaton allows you to add paths to the automaton but not to remove ones. Removing paths will be partially done by the "keep best

Figure 7.5: Automaton that has been normalized with the grammar of figure 7.4

paths" heuristic, if enabled. To go further, you will need to use the ELAG disambiguation functionality.

7.2.3 Normalization of clitic pronouns in Portuguese

In Portuguese, verbs in the future tense and in the conditional can be modified by the insertion of one or two clitic pronouns between the root and the suffix of the verb. For example, the sequence *dir-me-ão* (*they will tell me*), corresponds to the complete verbal form *dirão*, associated with the pronoun *me*. In order to be able to manipulate this underlying form, it is necessary to introduce it into the text automaton in parallel to the original form. Thus, the user can search one or the other form. The figures 7.6 and 7.7 show the automaton of a sentence after normalization of the clitics.

Figure 7.6: Text automaton without normalization

Figure 7.7: Normalized text automaton

The *Reconstrucao* program allows you to construct a normalization grammar for these forms for each text dynamically. The grammar thus produced can then be used for normalizing the text automaton. The configuration window of the automaton construction suggests an option "Build clitic normalization grammar" (cf. figure 7.10). This option automatically starts the construction of the normalization grammar, which is then used to construct the text automaton, if you have selected the option "Apply the Normalization grammar".

7.2.4 Keeping the best paths

An unknown word can perturb the text automaton by overlapping with a completely labeled sequence. Thus, in the automaton of figure 7.8, it can be seen that the adverb *aujourd'hui* overlaps with the unknown word *aujourd*, followed by an apostrophe and the past participle of the verb *huir*.

Figure 7.8: Ambiguity due to a sentence containing an unknown word

This phenomenon can also take place in the treatment of certain Asian languages like Thai. When words are not delimited, there is no other solution than to consider all possible combinations, which causes the creation of numerous paths carrying unknown words that are mixed with the labeled paths. Figure 7.9 shows an example of such an automaton of a Thai sentence.

Figure 7.9: Automaton of a Thai sentence

It is possible to suppress parasite paths. You have to select the option "Clean Text FST" in the configuration window for the construction of the text automaton (cf. figure 7.10). This option indicates to the automaton construction program that it should clean up each sentence automaton.

This cleaning is carried out according to the following principle: if several paths are concurrent in the automaton, the program keeps those that contain the fewest unlabeled tokens. For instance, the compound adverb *aujourd'hui* is preferred to the sequence made of *aujourd* followed by a quote and *hui*, because *aujourd* and the quote are both unlabeled

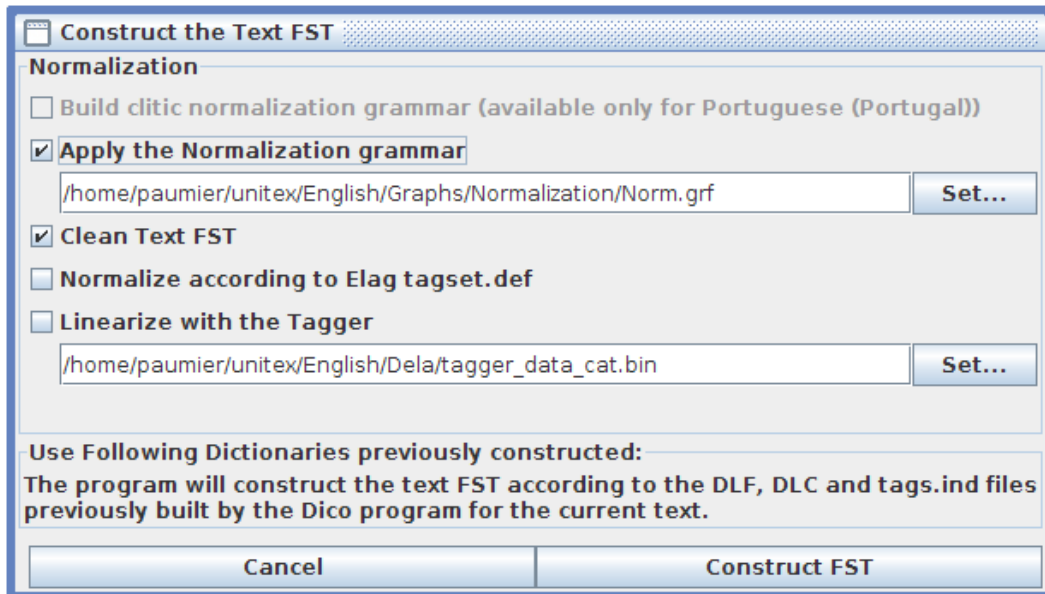

Figure 7.10: Configuration of the construction of the text automaton

tokens, while the compound adverb path does not contain any unknown word. Figure 7.11 shows the automaton of figure 7.9 after cleaning.

Figure 7.11: Automaton of figure 7.9 after cleaning

7.3 Resolving Lexical Ambiguities with ELAG

The ELAG program allows for applying grammars for ambiguity removal to the text automaton. This powerful mechanism makes it possible to write rules on independently from already existing rules. This chapter briefly presents the grammar formalism used by ELAG and describes how the program works. For more details, the reader may refer to [6] and [64].

7.3.1 Grammars For Resolving Ambiguities

The grammars used by ELAG have a special syntax. They consist of two parts which we call the *if* and *then* parts. The *if* part of an ELAG grammar is divided in two parts which are divided by a box containing the `<!>` symbol. The *then* part is divided the same way using the `<=>` symbol. The meaning of a grammar is the following: In the text automaton, if a path of the *if* part is recognized, then it must also be recognized by the *then* part of the grammar, or it will be withdrawn from the text automaton.

Figure 7.12: ELAG grammar `elag-tu.grf`

Figure 7.12 shows an example of a grammar. The *if* part recognizes a verb in the 2nd person singular followed by a dash and `tu`, either as a pronoun, or as a past participle of the verb `taire`. The *then* part imposes that `tu` is then regarded as a pronoun. Figure 7.13 shows the result of the application of this grammar on the sentence "*Feras-tu cela bientôt ?*". One can see in the automaton at the bottom that the path corresponding to `tu` past participle was eliminated.

Synchronization point

The *if* and *then* parts of an ELAG grammar are divided into two parts by `<!>` in the *if* part, and `<=>` in the *then* part. These symbols form a *synchronization point*. This makes it possible to write rules in which the *if* and *then* constraints are not necessarily aligned, as it is the case for example in figure 7.14. This grammar is interpreted in the following way: if a dash is found followed by `il`, `elle` or `on`, then this dash must be preceded by a verb, possibly

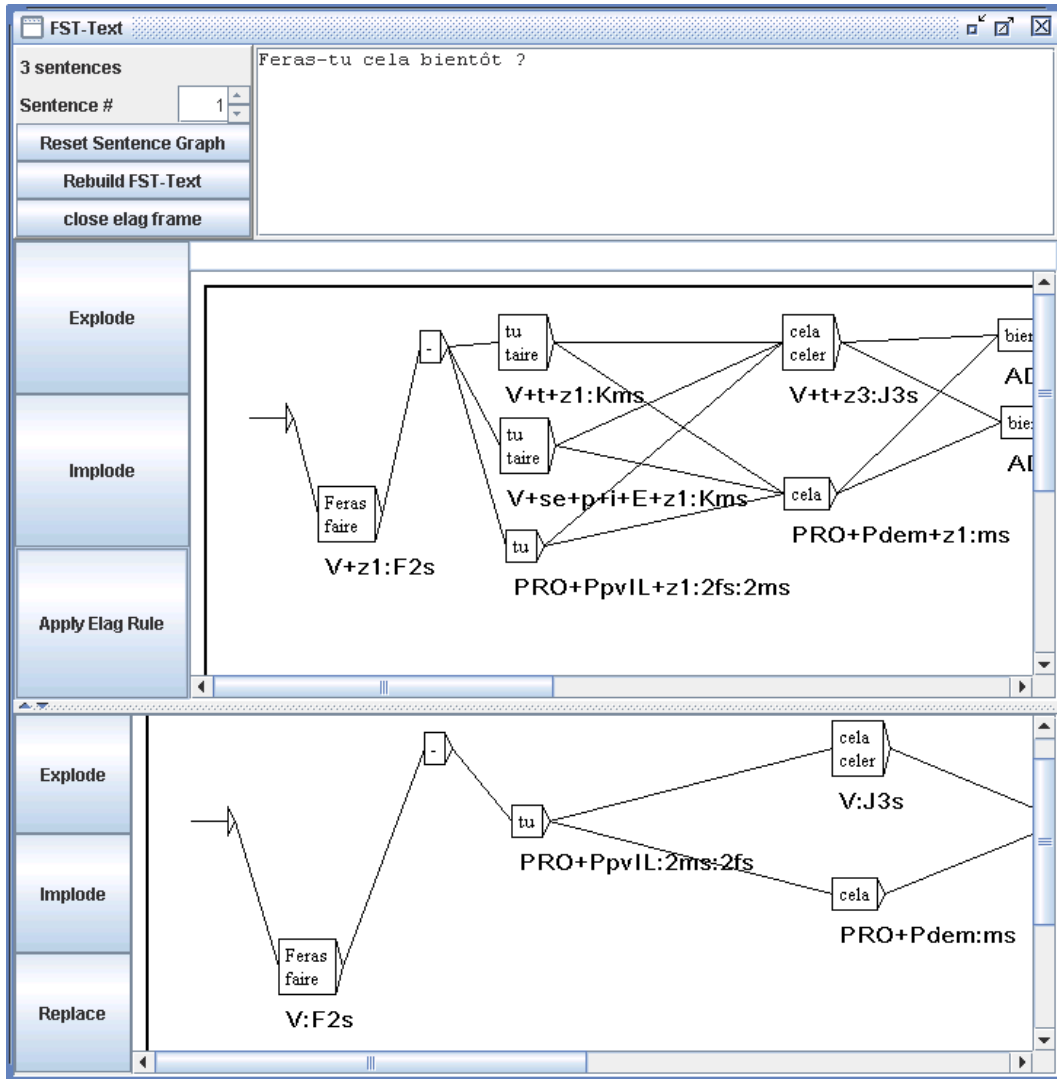

Figure 7.13: Result of applying the grammar in figure 7.12

followed by $-t$. So, if one considers the sentence of the figure 7.15 beginning with *Est-il*, one can see that all non-verb interpretations of *Est* were removed.

7.3.2 Compiling ELAG Grammars

Before an ELAG grammar can be applied to a text automaton, the grammar must be compiled in a `.rul` file. This operation is carried out via the "Elag Rules" command in the "Text" menu, which opens the windows shown in figure 7.16.

If the frame on the right already contains grammars which you don't wish to use, you can withdraw them with the " \ll " button. Then select your grammar(s) in the file explorer located

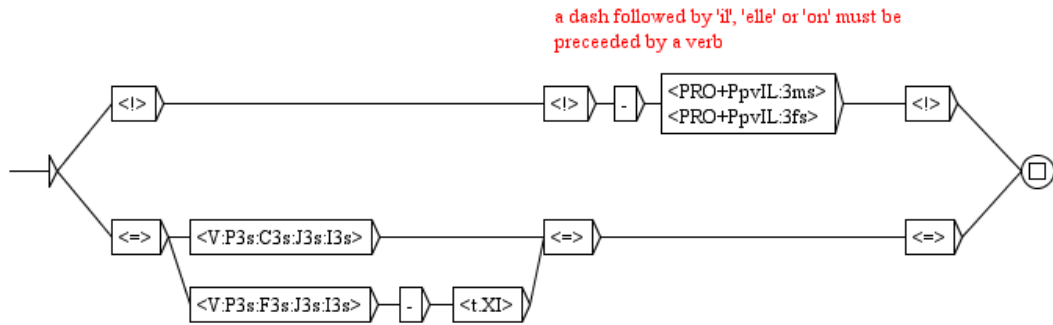

Figure 7.14: Use of the synchronization point

Figure 7.15: Result of the application of the grammar in figure 7.14

Figure 7.16: ELAG grammars compilation frame

in the left frame, and click on the ">>" button to add them to the list in the right frame. Then click on the "Compile" button. This will launch the `ElagComp` program which will compile the selected grammars and create a file named `elag.rul` by default.

If you have selected grammars in the right frame, you can search patterns within them by clicking on the "Locate" button. This opens the window "Locate Pattern" and automatically enters a graph name ending with `-conc.fst2`. This graph corresponds to the *if* part of the grammar. You can thus obtain the occurrences of the text to which the grammar will apply.

NOTE: The `-conc.fst2` file used to locate the *if* part of a grammar is automatically generated when ELAG grammars are compiled by means of the "Compile" button. It is thus necessary to have your grammar compiled before searching using the "Locate" button.

7.3.3 Resolving Ambiguities

Once you have compiled your grammar into an `elag.rul` file, you can apply it to a text automaton. In the text automaton window, click on the "Apply Elag Rule" button. A dialog box will appear which asks for the `.rul` file to be used (see figure 7.17). The default file is `elag.rul`. This will launch the `Elag` program which will try to resolve the ambiguity.

Once the program has finished you can view the resulting automaton by clicking on the "Open Elag Frame" button. As you can see in figure 7.18, the window is separated into two parts: The original text automaton can be seen on the top, and the result at the bottom.

Figure 7.17: Text automaton frame

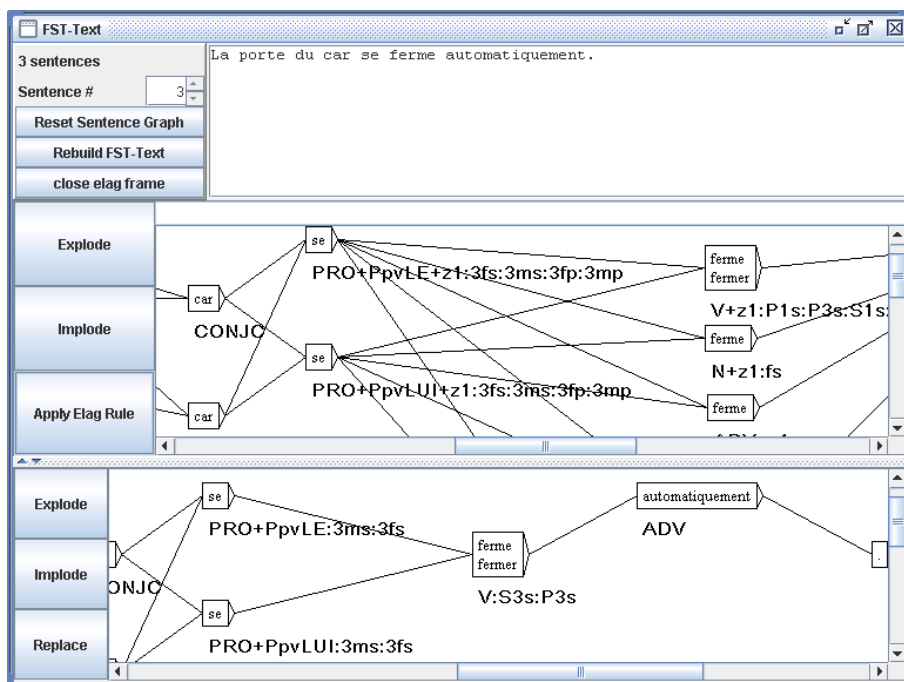

Figure 7.18: Splitted text automaton frame

Don't be surprised if the automaton shown at the bottom seems more complicated. This results from the fact that factorized lexical entries¹ were exploded in order to treat each inflectional interpretation separately. To refactorize these entries, click on the "Implode" button. Clicking on the "Explode" button shows you an exploded view of the text automaton.

If you click on the "Replace" button, the resulting automaton will become the new text automaton. Thus, if you use other grammars, they will apply to the already partially disambiguated automaton, which makes it possible to accumulate the effects of several grammars.

7.3.4 Grammar collections

It is possible to gather several ELAG grammars into a grammar collection in order to compile and apply them in one step. The sets of ELAG grammars are described in `.lst` files. They are managed through the window for compiling ELAG grammars (figure 7.16). The label on the top left indicates the name of the current collection, by default `elag.lst`. The contents of this collection are displayed in the right part of the window.

To modify the name of the collection, click on the "Browse" button. In the dialog box that appears, enter the `.lst` file name for the collection.

To add a grammar to the collection, select it in the file explorer in the left frame, and click on the "»" button. Once you have selected all your grammars, compile them by clicking on the "Compile" button. This will create a `.rul` file bearing the name indicated at the bottom right (the name of the file is obtained by replacing `.lst` by `.rul`).

You can now apply your grammar collection. As explained above, click on the "Apply Elag Rule" button in the text automaton window. When the dialog asks for the `.rul` file to use, click on the "Browse" button and select your collection. The resulting automaton is identical to that which would have been obtained by applying each grammar successively.

7.3.5 Window For ELAG Processing

At the time of disambiguation, the `Elag` program is launched in a processing window which displays the messages printed by the program during its execution.

For example, when the text automaton contains symbols which do not correspond to the set of ELAG labels (see the following section), a message indicates the nature of the error. In the same way, when a sentence is rejected (all possible analyses were eliminated by grammars), a message indicates the number of the sentence. That makes it possible to locate the source of the problems quickly.

¹Entries which gather several different inflectional interpretations, such as for example:
{se, .PRO+PpvLE:3ms:3fs:3mp:3fp}.

Evaluation of ambiguity removal

The assessment of the ambiguity rate is not based solely on the average number of interpretations per word. In order to get a more representative measure, the system also takes into account the various combinations of words. While instances of ambiguities are resolved, the `Elag` program calculates the number of possible analyses in the text automaton before and after the modification (which corresponds to the number of possible paths through the automaton). On the basis of this value, the program computes the average ambiguity by sentence and word. It is this last measure which is used to represent the ambiguity rate of the text, because it does not vary with the size of the corpus, nor with the number of sentences within. The formula applied is:

$$\text{lexical ambiguity rate} = \exp \frac{\log(\text{number-of-paths})}{\text{text-length}}$$

The relationship between the ambiguity rate before and after applying the grammars gives a measure of their efficiency. All this information is displayed in the ELAG processing window.

7.3.6 Description of the tag sets

The `Elag` and `ElagComp` programs require a formal description of the tag set to be used in dictionaries. This description consists essentially of an enumeration of all the parts of speech present in the dictionaries, with, for each of them, the list of syntactic and inflectional codes compatible with it, and a description of their possible combinations. This description must be contained in a file called `tagset.def` and placed in your working directory, in the `Elag` subdirectory of the language.

tagset.def file

Here is an extract of the `tagset.def` file used for French.

```
NAME french

POS ADV
.

POS PRO
flex:
pers   = 1 2 3
genre  = m f
nombre = s p
discr:
```

```

S <pers> <nombre>
T <pers> <nombre>
X 1 s # eusse dusse puisse fusse (-je)
Y 1 p
Y 2 <nombre>
K <genre> <nombre>
.

```

The # symbol indicates that the remainder of the line is a comment. A comment can appear at any place in the file. The file always starts with the word `NAME`, followed by an identifier (`french`, for example). This is followed by the `POS` sections for each part of speech. Each section describes the structure of the lexical tags of the lexical entries belonging to the part of speech concerned. Each section is composed of 4 parts which are all optional:

- `flex`: this part enumerates the inflectional codes belonging to the grammatical category. For example, the codes 1, 2, 3 which indicate the person of the entry are relevant for pronouns but not for adjectives. Each line describes an inflectional attribute (gender, time, etc.) and is made up of the attribute name, followed by the = character and the values which it can take. For example, the following line declares an attribute `pers` being able to taking the values 1, 2 or 3:

```
pers = 1 2 3
```

- `cat`: this part declares the syntactic and semantic attributes which can be assigned to the entries belonging to the part of speech concerned. Each line describes an attribute and the values which it can take. The codes declared for the same attribute must be exclusive. In other words, an entry cannot take more than one value for the same attribute.

On the other hand, all the tags in a given part of speech don't necessarily take values for all the attribute of the part of speech. For example, to define the attribute `niveau_de_langue` which can take the values `z1`, `z2` and `z3`, the following line can be written:

```
niveau_de_langue = z1 z2 z3
```

but this attribute is not necessarily present in all words.

- `discr`: this part consists of a declaration of a unique attribute. The syntax is the same as in the `cat` part and the attribute described here must not be repeated there. This part allows for dividing the grammatical category in *discriminating* sub categories in which the entries have similar inflectional attributes. For pronouns for example, a person feature is assigned to entries that are part of the personal pronoun sub category but not to relative pronouns. These dependencies are described in the `complete` part;

- `complete`: this part describes the inflectional part of the tags of the words in the current part of speech. Each line describes a valid combination of inflectional codes by their discriminating sub category (if such a category was declared). If an attribute name is specified in angle brackets (< and >), this signifies that any value of this attribute may occur. It is possible as well to declare that an entry does not take any inflectional feature by means of a line containing only the `_` character (underscore). So for example, if we consider that the following lines extracted from the section describing the verbs:

```
W
K <genre> <nombre>
```

They make it possible to declare that verbs in the infinitive (indicated by the `W` code) do not have other inflectional features while the forms in the past participle (`K` code) are also assigned a gender and a number.

Description of the inflectional codes

The principal function of the `discr` part is to divide a part of speech into subcategories having similar inflectional behavior. These subcategories are then used to facilitate writing the `complete` part.

For the legibility of the ELAG grammars, it is desirable that the elements of the same subcategory all have the same inflectional behavior; in this case the `complete` part is made up of only one line per subcategory. Let us consider for example the following lines from the pronoun description:

```
Pdem <genre> <nombre>
PpvI1 <genre> <nombre> <pers>
PpvPr
```

These lines mean:

- all the demonstrative pronouns (`PRO+Pdem`) have only a gender and a number;
- clitic pronouns in the nominative (`<PRO+PpvI1>`) are labelled grammatically in person, gender and number;
- the prepositional pronouns (`en, y`) do not have any inflectional feature.

All combinations of inflectional features and discriminant subcategories which appear in the dictionaries must be described in the `tagset.def` file; otherwise, the information in the corresponding entries will be discarded by ELAG.

If words of the same subcategory differ by their inflectional profile, it is necessary to write several lines into the `complete` part. The disadvantage of this method of description is that it becomes difficult to make the distinction between such words in an ELAG grammar.

If one considers the description given by the previous example of a `tagset.def` file, certain adjectives of French take a gender and a number, whereas others do not have any inflectional feature. This allows for coding fixed sequences like *de bonne humeur* as adjective, on the basis of their syntactic behavior.

Consider a French dictionary with such sequences as invariable adjectives without inflectional features. The problem is that if one wants to refer exclusively to this type of adjectives in a disambiguation grammar, the `<A>` symbol is not appropriate, since it will recognize all adjectives. To circumvent this difficulty, it is possible to deny an inflectional attribute by writing the `@` character right before one of the possible values for this attribute. Thus, the `<A:@m@p>` symbol recognizes all the adjectives which have neither a gender nor a number. Using this operator, it is possible to write grammars like those in figure 7.19, which imposes agreement in gender and number between a name and an adjective which suits². This grammar will preserve the correct analysis of sentences like: *Les personnes de bonne humeur m'insupportent*.

It is however recommended to limit the use of the `@` operator, because it harms the legibility of the grammars. It is preferable to distinguish the labels which accept various inflectional combinations by means of discriminating subcategories defined in the `discr` part.

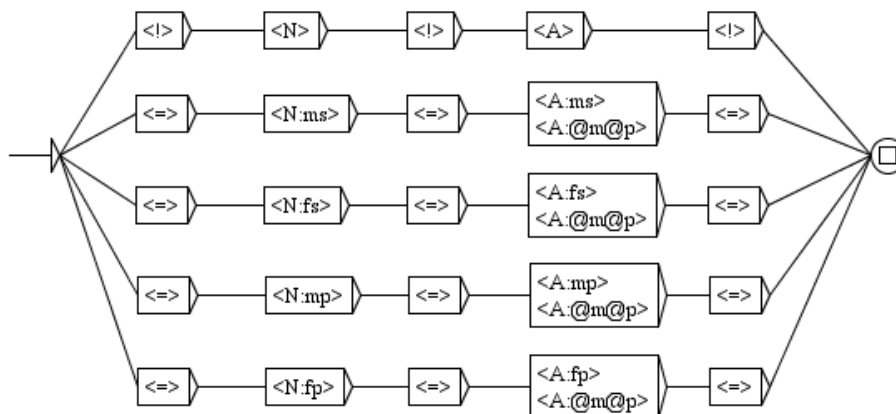

Figure 7.19: ELAG grammar that verifies gender and number agreement

Optional Codes

The optional syntactic and semantic codes are declared in the `cat` part. They can be used in ELAG grammars like other codes. The difference is that these codes do not intervene to

²This grammar is not completely correct, because it eliminates for example the correct analysis of the sentence: *J'ai reçu des coups de fil de ma mère hallucinants*.

decide if a label must be rejected as an invalid one while loading of the text automaton.

In fact optional codes are independent of other codes, such as for example the attribute of the language level (z_1 , z_2 or z_3). In the same manner as for inflectional codes, it is possible to deny an inflectional attribute by writing the `!` character right before the name of the attribute. Thus, with our example file, the `<A!gauche:f>` symbol recognizes all adjectives in the feminine which do not have the `gauche` code³.

All codes which are not declared in the `tagset.def` file are discarded by ELAG. If a dictionary entry contains such a code, ELAG will produce a warning and will withdraw the code from the entry.

Consequently, if two concurrent entries differ in the original text automaton only by undeclared codes, these entries will become indistinguishable by the programs and will thus be unified into only one entry in the resulting automaton.

Thus, the set of labels described in the file `tagset.def` file is compatible with the dictionaries distributed with Unitex, by factorizing words which differ only by undeclared codes, and this independently of the applied grammars.

For example, in the most complete version of the French dictionary, each individual use of a verb is characterized by a reference to the lexicon grammar table which contains it. We have considered until now that this information is more relevant to syntax than to lexical analysis and we thus don't have integrated them into the description of the tagset. They are thus automatically eliminated at the time when the text automaton is loaded, which reduces the rate of ambiguity.

In order to distinguish the effects bound to the tagset from those of the ELAG grammars, it is advised to proceed to a preliminary stage of normalization of the text automaton before applying disambiguation grammars to it. This normalization is carried out by applying to the text automaton a grammar not imposing any constraint, like that of figure 7.20. Note that this grammar is normally present in the Unitex distribution and precompiled in the file `norm.rul`.

Figure 7.20: ELAG grammar without any constraint

³This code indicates that the adjective must appear on the left of the noun to which it refers to, as is the case for *bel*.

The result of applying such a grammar is that the original is cleaned of all the codes which either are not described in the `tagset.def` file, or do not conform to this description (because of unknown grammatical categories or invalid combinations of inflectional features). By then replacing the text automaton by this normalized automaton, one can be sure that later modifications of the automaton will only be effects of ELAG grammars.

7.3.7 Grammar Optimization

Compilation of ELAG grammars by the `ElagComp` program consists in building an automaton whose language is the set of the sequences of lexical tags (or lexical analyses of a sentence) which are not accepted by the grammars. This task is complex and can take a lot of time. It is however possible to appreciably speed it up by observing certain principles at the time of writing gramars.

Limiting the number of branches in the *then* part

It is recommended to limit the number of *then* parts of a grammar to a minimum. This can reduce considerably the compile time of a grammar. Generally, a grammar having many *then* parts can be rewritten with one or two *then* parts, without a loss of legibility. It is for example the case of the grammar in figure 7.21, which imposes a constraint between a verb and the pronoun which follows it.

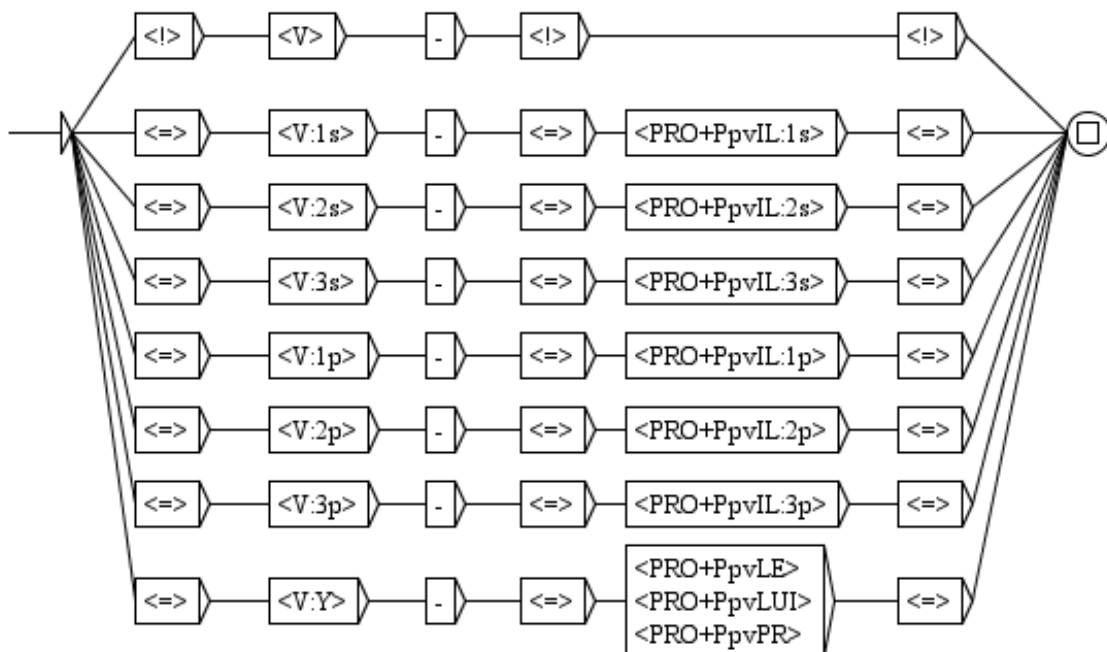

Figure 7.21: ELAG grammar checking verb-pronoun agreement

As one can see in figure 7.22, one can write an equivalent grammar by factorizing all the

then parts into only one. The two grammars will have exactly the same effect on the text automaton, but the second one will be compiled much more quickly.

Figure 7.22: Optimized ELAG grammar checking verb-pronoun agreement

Using lexical masks

It is better to use lemmas only when it is necessary. That is particularly true for some grammatical words, when their subcategories carry almost as much information as the lemmas themselves. In any case, it is recommended to specify its syntactic, semantic and inflectional features as much as possible. For example, with the dictionaries provided for French, it is preferable to replace lexical masks like `<je.PRO:1s>`, `<je.PRO+PpvIL:1s>` and `<je.PRO>` with the mask `<PRO+PpvI1:1s>`. Indeed, all these masks are identical insofar as they can recognize only the single entry of the dictionary `{ je, PRO+PpvIL:1ms:1fs }`. However, as the program does not deduce this information automatically, if all these features are not specified, the program will consider nonexisting labels such as `<je.PRO:3p>`, `<je.PRO+PronQ>` etc. in vain.

7.4 Linearizing text automaton with the tagger

By default, the text automaton contains many paths of tags because of lexical ambiguity. The linearization process consists in selecting a single path, a sequence of tags with one tag per token, and remove the others. The output of the process is a text automaton with a

single path (see section 7.6 for converting a linear automaton into linear text). The selection of a path depends on its score. The path with the best score is chosen and the others are removed. The score of a path is calculated using a statistical model trained on an annotated corpus. This model uses tagger data files generated by the TrainingTagger program (see section 13.44). For instance, you can see on Figure 7.23, the original text automaton of the French sentence *Les insectes nuisibles envahissent la maison*. The corresponding text automaton after linearization is shown on Figure 7.24.

Figure 7.23: Text automaton of *Les insectes nuisibles envahissent la maison*.

Figure 7.24: Text automaton linearized

7.4.1 Compatibility of the tagset

The tagset of the tagger is identical to that of the training corpus or is a variant (see below). However, in order to use the tagger on a text automaton, one should pay attention to tagset and morphology. The tagset of the model must be identical to that of the text automaton. For example, if the statistical model has been computed with the tag `DET` for the word `the`, the corresponding tag in the text automaton must be `DET`. Unitex provides functionality to modify word forms in the text, for example to normalize `doesn't` into `does not`. Applying replacing or normalization graphs could cause some morphological modifications on words. If such processing is applied to the text, it must have been applied to the training corpus as well. If these rules are not respected, the tagger might not be able to keep the good path from the text automaton.

The TrainingTagger program produces two variants of the tagger. The first one prunes transitions on the basis of grammatical, semantic, syntactic and inflectional codes (for example, `the.DET+Ddef:s` versus `the.DET+Ddef:p`). The second one prunes transitions on the

basis of grammatical, semantic and syntactic codes (that .DET+Ddem versus that .PRO+Pdem). This option makes the training quicker and inflectional features are not needed for all applications.

7.4.2 Use of the Tagger

In order to linearize the text automaton, you have to select the option "Linearize with the Tagger" in the configuration window for the construction of the text automaton (cf. figure 7.25). With this option, the program will linearize each sentence automaton. You must also select the tagger data file (with ".bin" extension) by clicking on the "Set" button. Tagger data file suffixed by "morph" is the first variant of the tagger (with inflectional codes) and the one suffixed by "cat" is the second variant (without inflectional codes). If you want to use the "morph" data, you also need to click on "Normalize according to Elag tagset.def" (for more details, see section 13.38 about Tagger program).

Figure 7.25: Configuration of the linearization of the text automaton

For instance, the text automaton, shown on Figure 7.24, is the output of linearization of the text automaton shown on Figure 7.23 with "cat" tagger data. Linearization of the automaton with "morph" tagger data is shown on Figure 7.26.

7.4.3 Creation of a new tagger

In order to create a new tagger for your language, you need to launch the TrainingTagger program on your own annotated corpus. The format of the annotated corpus is described in

Figure 7.26: Text automaton linearized with "morph" tagger data

14.10.1. As we discuss in Section 7.4.1, you need to pay attention on tagset and morphology. Before computing a statistical model, you have to decide which dictionaries and normalization graphs you will use to construct the text automaton. And then, you will have to do modifications on the annotated corpus if word forms or tagset do not match completely. For example, if the normalization graph transforms the word *jusqu'* into *jusque*, the corresponding word into the annotated corpus must be *jusque*.

A French tagger is distributed with Unitex. It has been created with an annotated corpus composed of tags without semantic and syntactic codes.

7.5 Manipulation of text automata

7.5.1 Displaying sentence automata

As we have seen above, the text automaton is in fact the collection of the sentence automata of a text. This structure can be represented using the format `.fst2`, also used for representing the compiled grammars. This format does not allow the system to directly display the sentence automata. Instead, the system uses the `Fst2Grf` program to convert the sentence automaton into a graph that can be displayed. This program is called automatically when you select a sentence in order to generate the corresponding `.grf` file.

The generated `.grf` files are not interpreted in the same manner as the `.grf` files that represent graphs constructed by the user. In fact, in a normal graph, the lines of a box are separated by the `+` symbol. In the graph of a sentence, each box represents either a lexical unit without a tag or a dictionary entry enclosed by curly brackets. If the box only represents an unlabeled lexical unit, this unit appears alone in the box. If the box represents a dictionary entry, the inflected form is displayed, followed in another line by the canonical form if it is different. The grammatical and inflectional information is displayed below the box as a transducer output.

Figure 7.27 shows the graph obtained for the first sentence of *Ivanhoe*. The words *Ivanhoe*, *Walter* and *Scott* are considered unknown words. The word *by* corresponds to two entries in the dictionary. The word *Sir* corresponds to two dictionary entries as well, but since the canonical form of these entries is *sir*, it is displayed because it differs from the inflected form by a lower case letter.

Figure 7.27: Automaton of the first sentence of *Ivanhoe*

7.5.2 Modifying the text automaton

It is possible to manually modify sentence automata, except those in the ELAG frame (lower frame). You can edit or erase boxes or transitions (cf. figure 7.28).

Figure 7.28: Modified sentence automaton

When a graph is modified, it is saved to the text file `sentenceN.grf`, where N represents the number of the sentence, but this operation does not modify the global text automaton. Thus, you can discard the manually modified graph and reset the automaton of that sentence from the global text automaton by clicking on the "Reset Sentence Graph" button.

When you select a sentence, if a modified graph exists for this sentence, Unitex displays it.

After you edited sentence automata, you can save your manual modifications to the global text automaton. In order to do that, click on the "Rebuild FST-Text" button. All sentences that have been modified are then replaced by their modified versions. The new text automaton is then automatically reloaded.

During the construction of the text automaton (7.2), all the modified sentence graphs in the text file are erased.

Manually resolving ambiguities

The text automaton may contain many paths of tags because of lexical ambiguity. You can either resolve ambiguities with ELAG Grammars or manually select the right paths for one or each graph of the sentence automaton. To do so, you can perform a right click on the box you want to keep when several boxes with different tags are proposed. The edges of the selected box will become more bold and the other boxes will appear grayed (see Figure 7.29).

Figure 7.29: Manually resolve ambiguities in sentence automaton

You can then click on the "Remove greyed states" button to keep only the selected boxes as in Figure 7.30.

Figure 7.30: Ambiguous boxes removed in sentence automaton

7.5.3 Display configuration

Sentence automata are subject to the same presentation options as the graphs. They use the same colors and fonts as well as the antialiasing effect. In order to configure the appearance of the sentence automata, you modify the general configuration by clicking on "Preferences..." in the "Info" menu. For further details, refer to section 5.3.5.

You can also print a sentence automaton by clicking on "Print..." in the "FSGraph" menu or by pressing <Ctrl+P>. Make sure that the printer's page orientation is set to landscape mode. To configure this parameter, click on "Page Setup" in the "FSGraph" menu.

7.6 Converting the text automaton into linear text

If the text automaton does not contain any lexical ambiguity, it is possible to build a text file corresponding to the unique path of the automaton. Go into the "Text" menu and click on "Convert FST-Text to Text...". You can set the output text file in the window as shown on Figure 7.31.

Figure 7.31: Setting output file for linearization of the text automaton

If the automaton is not linear, an error message will give you the number of the first sentence that contain ambiguity. Otherwise, the `Tfst2Unambig` program will build the output file according to the following rules:

- the output file contains one line per sentence;
- every line but the last is ended by `{S}`;

- for each box, the program writes its content followed by a space.

Figure 7.32: Example of a linear text automaton

NOTE: correcting spaces in the output text can only be done manually. If the original text is the one of the text automaton shown on Figure 7.32, the output text will be:

```
2 3 {cats,cat.N+Anl:p} {are,be.V:P2s:P1p:P2p:P3p} {white,white.A} .
```

7.7 Searching patterns in the text automaton

With the `LocateTfst` program, Unitex can perform search operations on the text automaton. The main advantages are that you can:

- benefit from ambiguity removal;
- benefit from the application of normalization grammar (see below);
- work at several morphological levels (multi-word units, simple words, morphemes). This is particularly interesting since you can now easily manipulate agglutinative languages like Korean (for Korean, see section 7.9).

The rules are very similar to the ones that apply to classical searches with `Locate`. Here are the differences:

- you cannot capture sequences with variables inside right contexts, as it is possible with `Locate` (see Figure 6.19, page 131)
- you cannot match things that are not in the text automaton: if the text automaton only contains a compound word tag and not its concurrent simple word tags, you won't be able to match simple words. For instance, in the sentence automaton shown on Figure 7.33, it is not possible to match `soixante` or `huit`, since there are no such paths.

Figure 7.33: Sentence automaton that cannot match with pattern `huit`

- matched sequences can differ from sequences that will appear in concordances. In fact, the text automaton may contain tags that do not correspond to the raw input text, in particular when a normalization grammar has been applied. For instance, if you look for the pattern `<le.DET>` in `80jours's` text automaton, you will obtain 7703 matches, while `Locate` only finds 5763 matches. This is because some words have been normalized, like `au` → `à le` or `du` → `de le`. So, when you look for `<le.DET>`, `LocateTfst` matches those tags that were added to the text automaton by the normalization grammar, and `Concord` uses the original sequence in the text to produce the concordance file, as shown on Figure 7.34.

Figure 7.34: A surprising concordance for pattern `<le.DET>`

- <TOKEN> does not match tokens as defined in `tokens.txt`. It matches any tag of the text automaton. Matched tags can be either longer than text tokens if they are compound word tags, or even shorter, if the text automaton contains morphological analysis like `un` as shown on Figure 3.28, page 74.
- even if you are not in morphological mode, you can define dictionary-entry variables (cf. section 6.4.4). Then, you can get from such variables the inflected form, lemma and codes of lexical entries, their POS code, semantic codes, inflectional codes and the value `zzz` of the `yyy` attribute if there is a code of the form `yyy=zzz`.

7.8 Table display

Sentence automata can be displayed in a table format. To do that, you just have to select the "Table" tab in the text automaton frame. You will then see a table as shown on Figure 7.35.

Form	POS sequence #1	POS sequence #2
DANS	DANS,dans.PREP+Dnom+z1

Figure 7.35: Table display

This table is not fully equivalent to the sentence automaton, since it only displays all possible POS for each simple or multiple word unit. It should be considered as an approximate compact view of information contained in the automaton. You can also filter grammatical/semantic codes to be displayed. Select "All" and you will see all codes. Select "Only POS category" and only first codes (supposed to represent the POS category) will be displayed. If you select "Use filter" and set a regular expression X , codes that do not contain something matched by X will be discarded. Any POSIX regular expression is accepted as filter. Check "Always show POS category", and as said, the POS category will be kept even if not matched by the filter, if any. For instance, Figure 7.36 shows a filtering result, obtained with the filter

^[A-Z] that matches any code starting with an uppercase letter, thus discarding codes like z1.

Form	POS sequence #1	POS sequence #2

7.9 The special case of Korean

Korean is an agglutinative language with a unique writing system: words are made of Hangul syllabic characters, but one Hangul character corresponds to several Jamo alphabetic characters. For instance, you can see on Figure 7.37 two examples of Hangul characters followed by their equivalent Jamo letter sequences.

Not all morphemes correspond to Hangul characters. For instance, Figure 7.38 shows a given token (shown in green) analyzed as a combination of two elements: a verb and a modifier. The point is that the modifier is only made of one Jamo letter that combines with the last Hangul character of the verb in order to give the last Hangul character of the whole word (in green).

능 생
 L—○ 사 | | ○

Figure 7.37: Hangul characters and their equivalent Jamo sequences

Figure 7.38: Decomposition of a Hangul character

As a consequence, it can be convenient for Korean users to write grammars with mixes of Hangul and Jamo characters. Thus, a grammar like the one shown on Figure 7.39 will match sequences like the one shown Figure 7.40.

Figure 7.39: A grammar with two Jamo letters

In Korean, the text automaton displays untagged tokens on a lavender-blue background.⁴

REMARKS:

1. Jamo letters are not in the Korean alphabet file (Alphabet.txt). DO NOT ADD THEM TO THIS FILE, because it would induce dysfunctions in programs.

⁴In Korean, versions before 3.1beta rev. 4272 display untagged tokens on a green background, as in Fig. 7.38 and 7.40.

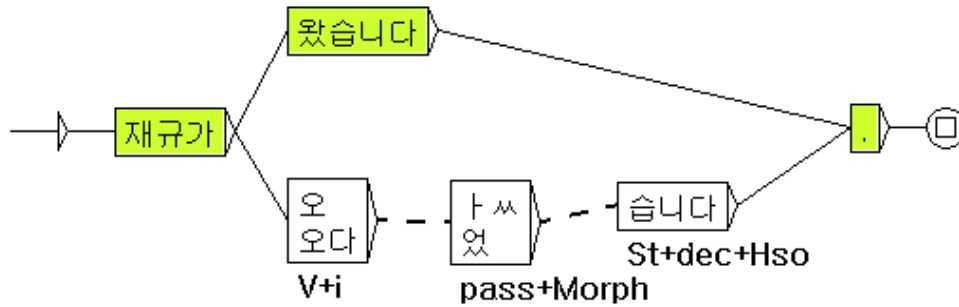

Figure 7.40: Sentence automaton matched by grammar of Figure 7.39

2. This alphabet file contains equivalences between some Chinese characters and some Hangul ones. In practice, if a grammar contains a Chinese character that has such an equivalent Hangul, it will match this Hangul in the text automaton. For instance, the grammar shown on Figure 7.41 will match the sentence of Figure 7.40, because the Korean alphabet file contains an equivalence for that character, as shown on Figure 7.42.

Chapter 8

Sequence Automaton

The construction of local grammars can be a long process during which the linguist repeated many times the same operations. The aim of the Seq2Grf program is to produce quickly and automatically local grammars.

This program can be used in command line mode or by clicking on "Construct Sequences Automaton" in the Text Menu. The use of the command Seq2Grf is described in section 13.34.

For a given document (TEILite or txt format files or SNT when preprocessed for this task with STOP tags) this programs builds a single automaton that recognizes all the sequences contained in the document.

Special attention should be paid to the establishment of the list of sequences that are recognized by the graph.

This chapter presents the file formats supported by the Seq2Grf program, the construction of the sequence automaton, and the use of wildcards.

8.1 Sequences Corpus

We call sequences corpus or qualified corpus a list of sequences of one or several words that we want to be recognized by only one local grammar graph.

This sequences corpus is stored in one single file wich must be from one of the following formats :

- raw text files in which sequences are delimited by end of line
- SNT files already processed with this menu : sequences will be delimited by the STOP tag.
- TEILite files in which sequences are delimited by the following xml tag :

```
<seg type="sequence">example</seg>
```

Since the corpus contains specific sequences, it must be done by hand. This means that you have to either write all the sequences in a raw text file and separate them by an end of line (figure 8.1), or insert the specific xml tag in an existing TEILite Document (figure 8.3). The preprocessing of TXT or XML Documents will produce a SNT file that is used for the build of the Sequence Automaton (figure 8.2). This File can be used as an input. The produced graph will only recognize the sequences that are correctly delimited. Production of local grammars is automatic only from a corpus of well-defined sequences. If you have such a corpus, then the time saved is considerable.

8.2 Usage

In order to create a sequence automaton, click on "Construct Sequence Automaton" in the "Text" menu. You will then see the window coming up as in figure 8.4.

This window will allow you to set the parameters to produce a sequence automaton. You have to follow these three steps :

- choose the sequence corpus : that can be a file which format is one of the three described in the previous section. The file format is automatically detected according to the file extension.
- set the specific options : Applying the beautifying algorithm will place each box so that the resulting graph is smaller and as easily readable as possible. The exact case matching will put literal tokens into braces in the graph so that the graph doesn't match tokens with same letters but with case differences.

You can set more options to produce a graph that allow approximate matching : you can set the number of jokers to be used to produce new sequences derived from the sequences of the original corpus, and what kind of joker can be used. All the details about the use of jokers is detailed in section 8.3

- choose the directory where the graph will be saved.

Figure 8.4: The sequence automaton menu

Figure 8.5: Options of the sequence automaton menu

You can see in figures 8.6 and 8.7 the graphes without wildcards produced without or with beautify.

Figure 8.6: Automaton without beautify option

Figure 8.7: Automaton with beautify option

8.3 Search by approximation

When you perform a locate operation on a text using a graph produced with the Seq2Grf program, you will find in the match occurrences only sequences present in the original sequence corpus. Some sequences close to those of the sequence corpus might appear in the text and be ignored because they are not in the sequence corpus. These sequences should be included in the sequence automaton. In order to find these sequences, you can produce a graph that recognize all the sequences from the sequence corpus, plus derived sequences that are the result of the application of three kind of wildcards. Each wildcard makes it possible to apply an operation to generate new sequences.

- insertion : for each sequence, add to the automaton all the sequences where <TOKEN> was inserted between two words of the original sequence.
- replacement : for each sequence, add to the automaton all the sequences where i tokens have been replace by <TOKEN>
- deletion : for each sequence, add to the automaton all the sequences where a token has been deleted

Each of these operations can be applied several times to the original sequences. Applying this grammar to a text will introduce approximations in the search of the sequences in the text.

When wildcards are used, the produced graphs follow these rules :

- both original and derived sequences are included in the automaton
- no empty sequence nor sequence made only with wildcards will be added to this graph (such sequences could be produced by deletions or replacements on short sequences)

- no insertion of a wildcard at the head or tail of a sequence
- every token of a sequence including the first and last can be replaced by a wildcard

The graphs produced using wildcard contain many erroneous sequences and must be confronted with corpora by a locate to keep only the relevant sequences. These sequences might be used to produce a new graph you might want to keep.

The graph in figure 8.8 was produced with replacement of 1 token and with the beautify option activated.

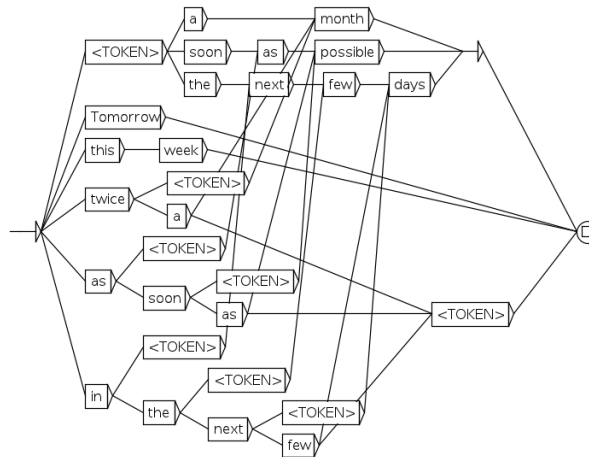

Figure 8.8: Automaton with one replacement allowed

Chapter 9

Lexicon-grammar

The tables of lexicon-grammar are a compact way for representing syntactical properties of the elements of a language. It is possible to automatically construct local grammars from such tables, due to a mechanism of parameterized graphs.

In the first part of the chapter the formalism of tables is presented. The second part describes parameterized graphs and a mechanism of automatically lexicalizing them with lexicon-grammar tables.

9.1 Lexicon-grammar tables

Lexicon-grammar is a methodology developed by Maurice Gross and the LADL team ([9], [10], [39], [52], [50], [51], [49], [48], [45], [44], [43], [42], [41], [66], [87]) based on the following principle: every verb has an almost unique set of syntactical properties. Due to this fact, these properties need to be systematically described, since it is impossible to predict the exact behavior of a verb. These descriptions are represented by matrices where rows correspond to verbs and columns to syntactical properties. The considered properties are formal properties such as the number and nature of allowed complements of the verb and the different transformations the verb can undergo (passivization, nominalisation, extraposition, etc.). The matrices, or tables, are mostly binary: a + sign occurs at the intersection of a row and a column of a property if the verb has that property, a – sign if not. More information in <http://infolingu.univ-mlv.fr>, including some lexicon-grammar tables that you can freely download.

This type of description has also been applied to adjectives ([69]), predicative nouns ([34], [35], [33], [40], [84]), adverbs ([46], [71]), as well as frozen expressions, in many languages ([14], [26], [27], [76], [77], [81], [91], [92], [93], [85], [82], [47]).

Figure 9.1 shows an example of a lexicon-grammar table. The table contains verbs that, among other definitional properties, do not admit passivization.

Figure 9.1: Lexicon-grammar Table 32NM

9.2 Conversion of a table into graphs

9.2.1 Principle of parameterized graphs

The conversion of a table into graphs is carried out by a mechanism involving parameterized graphs. The principle is the following: a graph that describes the possible constructions is constructed manually. That graph refers to the columns of the table in the form of parameters or variables. Afterwards, for each line of the table a copy of this graph is constructed where the variables are replaced with the contents of the cell at the intersection of line and the column that corresponds to the variable. If a cell of the table contains the + sign, the corresponding variable is replaced by <E>. If the cell contains the - sign, the box containing the corresponding variable is removed, interrupting the paths through that box. In all other cases the variable is replaced by the contents of the cell.

9.2.2 Format of the table

The lexicon-grammar tables are usually encoded with the aid of a spreadsheet like OpenOffice.org Calc ([75]). To be usable with Unitex, the tables have to be encoded in Unicode text format in accordance with the following convention: the columns need to be separated by a

tab and the lines by a newline.

In order to convert a table with OpenOffice.org Calc, save it in text format (.csv extension). You can then parameterize the output format with a window as shown on Figure 9.2. Choose "Unicode", select tabulation as column separator and do not set any text delimiter.

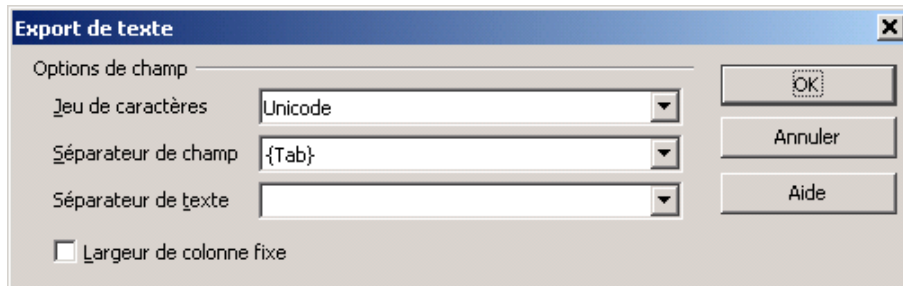

Figure 9.2: Saving a table with OpenOffice.org Calc

During the generation of the graphs, Unitex skips the first line, considering that it contains the headings of the columns. It is therefore necessary to ensure that the headings of the columns occupy exactly one line. If there is no line for the heading, the first line of a table will be ignored anyway, and if there are multiple heading lines, from the second line on they will be interpreted as lines of the table.

9.2.3 Parameterized graphs

Parameterized graphs are graphs with variables referring to the columns of a lexicon-grammar table. This mechanism is usually used with syntactic graphs, but nothing prevents the construction of parameterized graphs for inflection, preprocessing, or for normalization.

Variables that refer to columns are formed with the @ symbol followed by the name of the column in capital letters (the columns are named starting with A).

Example: @C refers to the third column of the table.

Whenever a variable takes the value of a + or - sign, the - sign corresponds to the removal of a path through that variable. It is possible to swap the meaning of these signs by typing an exclamation mark in front of the @ symbol. In that case, the path is removed when there is a + sign and kept where there is a - one. In all other cases, the variable is replaced by the content of the table cell.

The special variable @% is replaced by the number of the line in the table. The fact that its value is different for each line allows for its use as a simple characterization of a line. That variable is not affected by an exclamation point to the left of it.

Figure 9.3 shows an example of a parameterized graph designed to be applied to the lexicon-grammar table 31H presented in figure 9.4.

Figure 9.3: Example of parameterized graph

Figure 9.4: Lexicon-grammar table 31H

9.2.4 Automatic generation of graphs

In order to be able to generate graphs from a parameterized graph and a table, first of all the table must be opened by clicking on "Open..." in the "Lexicon-Grammar" menu (see figure 9.5). The table must be in Unicode text format.

The selected table is then displayed in a window (see figure figure 9.6). If it does not appear

Figure 9.5: Menu "Lexicon-Grammar"

on your screen, it may be hidden by other Unitex windows.

NO =: N-hum	NO =: V-n	Aux =: avoir	<ENT>	NO est V-ant	NO est Vpp	NOpc lui V	NO V de NOpcNhum V sur...	Ni
-	-	+	abando...	-	-	-	-	-

+	-	+	bander	-	-	-	+	-

Figure 9.6: Displaying a table

To automatically generate graphs from a parameterized graph, click on "Compile to GRF..." in the "Lexicon-Grammar" menu. The window in figure 9.7 shows this.

In the "Reference Graph (in GRF format)" frame, indicate the name of the parameterized graph to be used. In the "Resulting GRF grammar" frame, indicate the name of the main graph that will be generated. This main graph is a graph that invokes all the graphs that are going to be generated. When launching a search in a text with that graph, all the generated graphs are simultaneously applied.

The "Name of produced subgraphs" frame is used to set the name of each graph that will be generated. Enter a name containing @%, because for each line of the table, @% will be replaced the line number, which guarantees that each graph name will be unique. For example, if the main graph is called "TestGraph.grf" and if subgraphs are called "TestGraph_@%.grf", the graph generated from the 16th line of the line will be named "TestGraph_0016.grf".

Figures 9.8 and 9.9 show two graphs generated by applying the parameterized graph of figure 9.3 at table 31H.

Figure 9.7: Configuration of the automatic generation of graphs

Figure 9.10 shows the resulting main graph.

Figure 9.8: Graph generated for the verb *archaïser*

Figure 9.9: Graph generated for the verb *badauder*

Figure 9.10: Main graph referring to all the generated graphs

Chapter 10

Text alignment

The principle of text alignment is simple: aligning two (or more) texts, one supposed to be the source, and the other(s) supposed to be its translation(s). The alignment is made at the sentence level, because word alignment is not possible yet, and certainly not relevant. Then, one can look for an expression *A* in one of the texts and look for its translations in the sentences aligned with those containing occurrences of *A*.

To include such a functionality into Unitex, Patrick Watrin integrated the Open Source text alignment tool XAlign, developed at the LORIA ([68]). In this chapter, we will explain how to use the alignment module. The reader interested in details about the integration of XAlign can consult [23] or [78], and [95] for an illustration of what can be done with this module.

10.1 Loading texts

First, you need to select your 2 texts. To do that, go into "XAlign>Open files...", and you will see the frame shown on Figure 10.1. You provide texts under two formats: raw unicode text (as you do for your corpus) or TEI-encoded texts (an XML format; see [55]). In the last text field, you can select a XML alignment file, if you have already built one. If you select a raw text, Unitex will need to build a basic TEI version of it (for more details, see section 13.51 about the XMLizer program). So, when you click on "OK", you will be asked to provide a XML file name as shown on Figure 10.2. Then, Unitex builds the XML versions of your texts, if needed, and displays the frame shown on Figure 10.3. As you can see, each text is presented as a list, each cell representing a sentence.

Figure 10.1: Text alignment selection frame

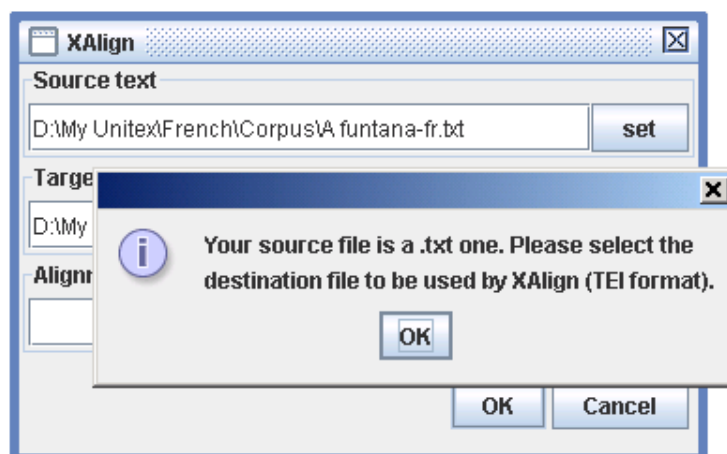

Figure 10.2: Warning about raw texts

Figure 10.3: Text alignment frame

10.2 Aligning texts

Once you have loaded your texts, you can align them by clicking on the "Align" button. You will be asked to provide the name of the XML file that will contain all the information about the alignment. Then, Unitex launches the XAlign program and you will visualize the alignment under the form of red links between aligned sentences, as shown on Figure 10.4.

You can edit the alignment links with the mouse. Clicking on a link removes it. To add a link (or remove it, if it already exists), click on one sentence (in the text you want, source or destination), and then move your mouse over the corresponding sentence in the other text. The link about to be added will appear in yellow, as shown on Figure 10.5. When you click, the link is actually added and becomes red. When you have made all your corrections, you can save your modified alignment using the "Save alignment" and "Save alignment as..." buttons.

An interesting feature of XAlign is that it is *reentrant*. It means that you can take an existing alignment as a set of mandatory links in input of the alignment process. This can be useful if you want to work with *cognates*. For more details about cognates and XAlign, see discussion in [78].

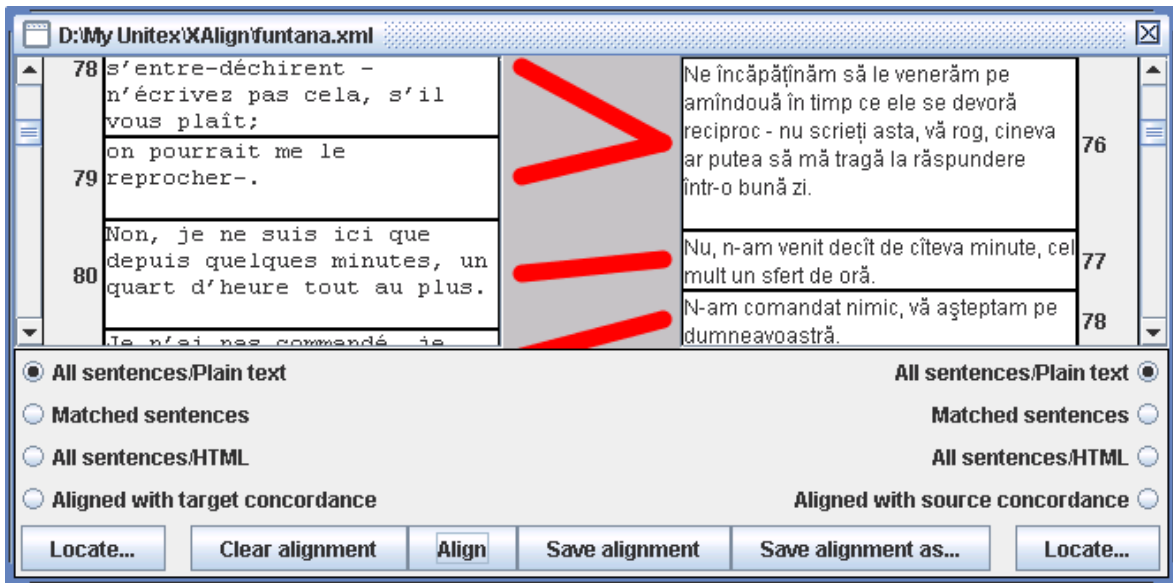

Figure 10.4: Aligned sentences

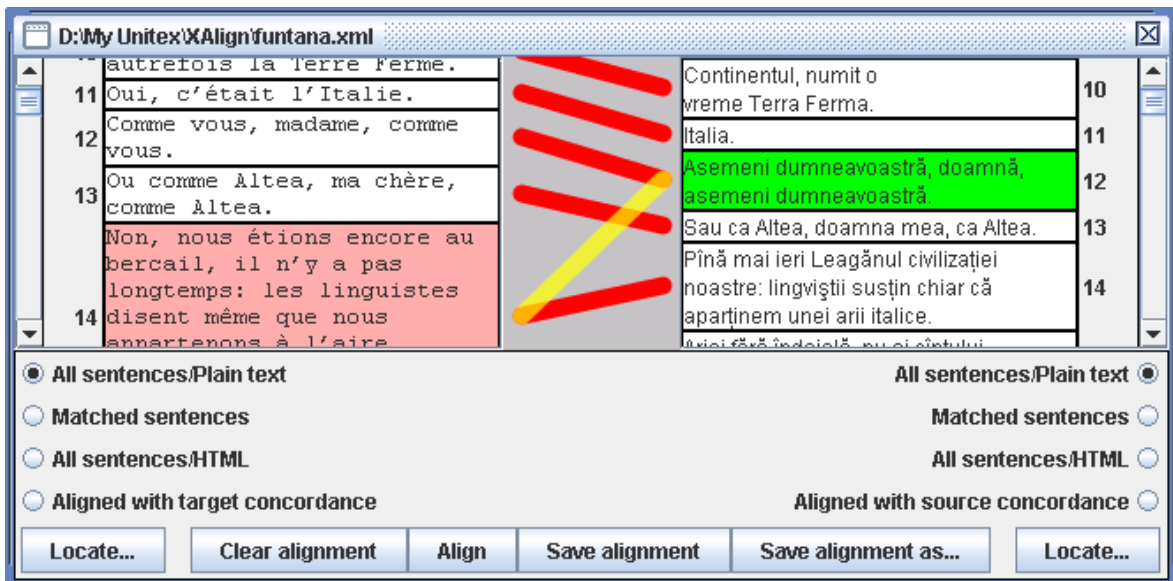

Figure 10.5: Adding a link

10.3 Pattern matching

You can perform pattern matching queries on any of your texts, by clicking on its "Locate" button. The first time you click, Unitex will ask you to build a working version of your text, as shown on Figure 10.6. This text version will be preprocessed according to the text language (in particular, the default dictionaries will be applied).

WARNING: the text language is determined on the basis of the path name. For instance, if your text file is located in `.../MyUnitex/Klingon/Corpus`, the language will be considered to be `Klingon`. So, if your text is not in a subdirectory of your personal working directory, its language will not be identified.

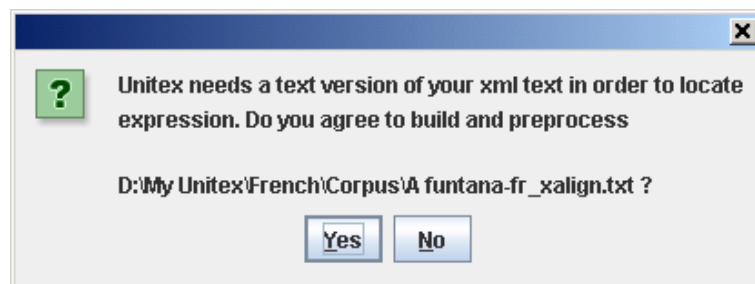

Figure 10.6: Unitex needs to build a working version of your text

Figure 10.7: Pattern matching frame for aligned texts

Once Unitex has created and preprocessed the working version of the text, you can perform

your query using the frame shown on Figure 10.7. As the matching operation is performed by the `Locate` program, you can perform the same queries than you would perform on a normal corpus. The only restriction is that you cannot exploit the outputs of your grammars, if any.

For instance, let us lookup for the pattern `<manger>` (*to eat*) in the French text of our example. First, we see no result, because we have not changed yet the display mode for the French text, which by default is "All sentences/Plain text". Clicking on "Matched sentences", we only see sentences that contain occurrences, highlighted as usual in blue, as shown on Figure 10.8. Clicking on "All sentences/HTML" will display all sentences, highlighting occurrences in blue.

Figure 10.8: Displaying matched sentences

To exploit parallel texts, it is then interesting to retrieve sentences aligned with matched sentences. This can be done by selecting *for the other text*, the display mode "Aligned with source concordance". In this mode, Unitex filters sentences that are not linked to matched sentences in the source text. So, it is easy to lookup for an expression in one text and to find the corresponding sentences in the other, as shown on Figure 10.9.

Figure 10.9: Displaying matched sentences and sentences they are linked to

Chapter 11

Compound word inflection

MULTIFLEX is a multi-lingual Unicode-compatible platform for automatic inflection of *multi-word units* (MWUs), also known as *compound words*. It is meant in particular for the creation of morphological dictionaries of MWUs. It implements a unification-based formalism ([89]) for the description of inflectional behavior of MWUs which supposes the existence of a module for the inflectional morphology of simple words.

In this chapter, we present the notion of multi-word unit and we describe the method to inflect them with MULTIFLEX.

This chapter is derived from the MULTIFLEX manual, written by Agata Savary, the author of MULTIFLEX.

11.1 Multi-Word Units

Multi-word units (MWUs) encompass a bunch of hard-to-define and controversial linguistic objects (cf. [53], [18]). Their numerous linguistic and pragmatic definitions ([5], [22], [67], [4], [37], [3], [90], [38], [13]) invoke three major points:

- they are composed of two or more words
- they show some degree of morphological, distributional or semantic non-compositionality
- they have unique and constant references

However, the basic notions (a word, a reference, the non-compositionality) and measures (degree of non-compositionality) used in those definitions are themselves controversial.

Pragmatically, we consider a MWU as a contiguous sequence of *graphical units* which, for some application-dependent reasons, has to be listed, described (morphologically, syntactically, semantically, etc.) and processed as a unit.

11.1.1 Formal Description of the Inflectional Behavior of Multi-word Units

The main issue in MULTIFLEX is the inflectional morphology of MWUs. This phenomenon has been linguistically analyzed for English, Polish and French in [88].

Obviously, a reliable inflection processing of single words is a necessary condition for the inflection processing of MWUs. However, this condition is rarely a sufficient one. For example, in order to obtain the plural form of

- *battle cry*
- *battle royal*
- *battle of nerves*

in English, not only do we need to know how to generate the plural of *battle*, *royal* and *cry*, but also to know how different inflected forms of these constituents combine:

- *battle cries*
- *battle royals, or battles royal,*
- *battles of nerves*

but not

- * *battles cries*
- * *battles royals*
- * *battles of nerve_*

Formally, a fully explicit description of the inflectional paradigms of MWUs requires an answer to the following questions:

- What is the MWU's morphological class (noun, adjective, etc.) and thus what inflection categories (number, gender, case, etc.) are relevant to it? [80] argue for a morphosyntactically motivated definition of morphological classes: a morphological class should fully determine the inflection categories the word inflects for as well as those that are lexically fixed for the word, e.g. in Polish, a noun has a gender and inflects for number and case.
- What are the exceptions to the inflection categories determined above? E.g. in Polish
 - *wybory powszechne*
(general election)

is a compound noun but it doesn't have a singular form (although its head word *wybory* does).

- What are the inflectional characteristics (base form, morphological class, inflection paradigm, etc.) of the single constituents of the MWU? E.g. in French, *porte* (door) is an uninflected verb in

– *porte-avion*
(aircraft carrier)

while it is an inflected noun in

– *porte-fenêtre*
(French window)

which takes an *s* in plural

– *portes-fenêtres*

- How should we combine the inflected forms of the single constituents in order to generate the inflected forms of the whole compound? E.g. to inflect *battle of nerves* and *battle cry* in number we need to inflect the first and the last constituent, respectively.

11.1.2 Lexicalized vs. Grammar-Based Approach to Morphological Description

A previous study ([88]) has confirmed the status of MWUs as units on the frontier between morphology and syntax. Their compound structure suggests productivity which can hardly be processed without a grammar-based approach. However some of their morphological, syntactic and semantic properties exclude their processing merely in terms of the properties of their constituents. For example, in both examples below:

- *chief justice*
- *lord justice*

there are few automatically accessible hints indicating that the former one is morphologically a standard English *Noun Noun* phrase taking an *s* at its last constituent in plural, while the plural of the latter has three variants:

- *chief justices*
- *lord justices*, *lords justice*, *lords justices*

Thus, at least one of the above examples has to be considered as lexicalized in order for the automatic morphological processing to be reliable.

MULTIFLEX implements a unification-based formalism for the description of the inflectional behavior of MWUs presented in [89]. Its features are described in section 11.2. This formalism requires the description to be *fully* lexicalized: each MWU listed in a dictionary

obtains a code (e.g. *NC_NN*, *NC_NN2*, etc.) representing its inflectional paradigm, for instance, in the DELA-like format:

```
aircraft carrier(carrier.N1:s),NC_NN
chief justice(justice.N1:s),NC_NN
lord(lord.N1:s) justice(justice.N1:s),NC_NN2
...
```

However, only a few codes, which can be seen as a phrase grammar of the language, represent the big majority of all MWUs. Thus, the lexicalization of the description mainly consists of pointing out the MWUs which respect or don't respect the "grammar".

11.2 Formalism for the Computational Morphology of MWUs

In [89] was proposed a formalism for describing the morphological paradigms of MWUs. It has been based on studies of English, Polish and French, and further tested for Serbian [59] and Greek [30]. It consists of a language-independent kernel which is to be completed by a set of morphological elements characteristic for the given language. In this section we give an in-depth description of this formalism.

11.2.1 Morphological Features of the Language

When processing MWUs of a given language we have to provide some general data about that language. These data are included in two textual files.

The `Morphology.txt` file gives the morphological classes (noun, adjective,...), categories (number, gender, case,...) and values (masculine, feminine, singular, nominative,...). Consider the following example:

```
Polish
<CATEGORIES>
Nb: sing, pl
Case: Nom, Gen, Dat, Acc, Inst, Loc, Voc
Gen: masc_pers, masc_anim, masc_inanim, fem, neu
<CLASSES>
noun: (Nb,<var>),(Case,<var>),(Gen,<fixed>)
adj:(Nb,<var>),(Case,<var>),(Gen,<var>)
adv:
```

The above file says that, for Polish, three inflection categories are considered: the number (*Nb*), the case (*Case*) and the gender (*Gen*). Each category is given an exhaustive list of its possible values (singular and plural for number, etc.). Further, each morphological class is described with respect to the categories it inflects for, and those that are fixed for it. For example, a noun inflects for number and case, and has a (fixed) gender. The presence of

such a file is necessary if we wish to express the fact that a certain word inflects for number, gender or case, without having to explicitly enumerate each time which inflectional values (singular, plural, masculine, etc.) it can take.

Similarly, for French the `Morphology.txt` file may be as follows:

```
French
<CATEGORIES>
Nb: s, p
Gen: m, f
<CLASSES>
noun: (Nb,<var>),(Gen,<var>)
adj:(Nb,<var>),(Gen,<var>)
adv:
```

However, in the existing systems for computational morphology, such a description of classes, categories and values is not always present. For example, according to the DELA conventions ([20]) the morphological values of each simple word are plain sequences of characters (e.g. *ms* for masculine singular) without any explicit mention of their corresponding categories. In order for the program to be compatible with such systems, we use a list (contained in a file called `Equivalences.txt`) that describes which foreign inflectional feature corresponds to which category-value pair in our description. For example, the following lists:

<i>Polish</i>	<i>French</i>
<i>s : Nb = sing</i>	<i>s : Nb = s</i>
<i>p : Nb = pl</i>	<i>p : Nb = p</i>
<i>M : Case = Nom</i>	<i>f : Gen = f</i>
<i>D : Case = Gen</i>	<i>m : Gen = m</i>
<i>C : Case = Dat</i>	
<i>B : Case = Acc</i>	
<i>I : Case = Inst</i>	
<i>L : Case = Loc</i>	
<i>V : Case = Voc</i>	
<i>o : Gen = masc_pers</i>	
<i>z : Gen = masc_anim</i>	
<i>r : Gen = masc_inanim</i>	
<i>f : Gen = fem</i>	
<i>n : Gen = neu</i>	

describe the equivalences between the previous `Morphology.txt` file for Polish and French, respectively, and the single-character features that might be used in DELA dictionaries for those languages under Unitex.

11.2.2 Decomposition of a MWU into Units

The notion of an elementary graphical unit is controversial and varies across languages and NLP systems. For instance in Unitex an alphabet, i.e. a set of characters, is first defined for each language. Each non alphabet character is called a separator. A graphical unit is then either a single separator (usually a punctuation mark, a digit, etc.) or a contiguous sequence of alphabet characters (e.g. *aujourd'hui* in French consists, according to this definition, of 3 units). In other systems a graphical unit may contain a punctuation mark (e.g. *c'est-à-dire*), or a limit between two graphical units may occur within a sequence of alphabet characters (*widział|bym*, cf [80]).

This variety of possible definitions of a graphical unit obviously has an impact on the definition of a multi-word unit. However, we wish our formalism for MWUs to be adaptable to different morphological systems for “simple words”. Thus, the definition of a graphical unit is a parameter to our system: each time MULTIFLEX is used with an external module for single units, this module has to decide how a sequence of characters is to be divided into units.

In our formalism, units are referred to by numerical variables \$1, \$2, \$3, etc. For example with Unitex, a sequence like

- *Athens '04*

consists of five constituents referred to in MULTIFLEX as:

\$1 = *Athens*
 \$2 = <space>
 \$3 = '
 \$4 = 0
 \$5 = 4

Each simple unit subject to inflection within a MWU has to be morphologically identified. The identification means providing sufficient data so that any inflected form of the same item may be generated on demand. For instance in:

- *mémoire vive*

we need to know that *vive* is the feminine singular form of a lemma, and we have to be able to generate the feminine plural form of the same lemma, *vives*. We suppose that the external module for single units working with MULTIFLEX is responsible for such identification and generation of inflected forms of single units.

In Unitex, the generation of forms is strongly inspired by the DELA system ([20]). In order to be able to generate one or more inflected forms of a word we have to know:

- its lemma

- its inflection paradigm (called inflection code)
- the inflection features of forms to be generated

Thus, within the Unitex/MULTIFLEX interface the description of a single unit is done as follows:

- *vive(vif.A54:fs)*

where *A54* is the inflection code of *vif* and *fs* is the DELA-style description using morphological features appearing in `Equivalences.txt` file (cf section 11.2.1). Knowing that *vive* is a feminine singular form of *vif* we may demand the generation of its plural without having to explicitly indicate the plural of which gender we are interested in: since we only wish to change the number, the gender remains as in the original word *vive*, i.e. feminine.

11.2.3 Inflection paradigm of a MWU

The morphological description of MWUs in our formalism is inspired by the DELA system in the sense that:

- each MWU is attributed an inflection code
- a MWU's inflection code explicitly describes each inflected form of a MWU in terms of actions to be performed on the lemma, and inflectional features to be attached to each form

In the Unitex-interfaced version, MULTIFLEX uses inflection codes represented as Unitex graphs compiled into the `.fst2` format. For example, Figure 11.1 contains the inflection graph for *battle royal*.

Figure 11.1: Inflection graph for *battle royal*

According to the Unitex convention, three constituents are present in *battle royal*: *battle* referred to as *\$1*, a space referred to as *\$2*, and *royal* referred to as *\$3*. If a variable appears alone in a box the constituent has to be the same as in the lemma of the MWU. For instance, *<\$3>* in the uppermost path means that the unit *royal* is to be recopied as such. If the variable is

accompanied by a set of category-feature equations, the constituent has to be inflected to the required form. E.g. $\langle \$3:Nb=p \rangle$ means that the plural form of *royal* is needed.

In order to generate all inflected forms of the MWU we have to explore all the paths existing in the graph. Each path starts at the leftmost right arrow and ends at the final encircled box. Each time we come to a node we perform the action contained in the box (a recopy or an inflection of a constituent) and we accumulate the morphological features contained under the box. The total of the accumulated node outputs should result in the complete morphological description of the inflected form.

For example in the graph on Figure 11.1 if we follow the intermediate path shown on Figure 11.2:

Figure 11.2: One path of the inflection graph for *battle royal*

we recopy *battle* ($\$1$) and the space ($\2), and we put *royal* into plural, which yields the plural form *battle royals* of the whole MWU. As the graph on Figure 11.1 contains three different paths the whole set of inflected forms generated for *battle royal* would be:

battle royal $\langle Nb=s \rangle$
battle royals $\langle Nb=p \rangle$
battles royal $\langle Nb=p \rangle$

After rewriting these forms into the Unitex DELACF format we obtain the following entries:

battle royal,*battle royal.N:s*
battle royals,*battle royal.N:p*
battles royal,*battle royal.N:p*

Note that this description is independent of the way we generate inflected forms of single words because we suppose that this problem is handled by an existing external morphological system for single words. In the Unitex-interfaced version of MULTIFLEX, we would generate the plural of *royal* due to the fact that its lemma is known as having the inflection code *N1* represented on Figure 11.3.

In an inflection paradigm of a MWU, each constituent is accompanied only by those morphological categories which it should inflect for. The categories that remain unchanged don't have to be mentioned. For instance, in *bateau-mouche* in French (a Paris-style riverboat), both noun constituents have their gender set but they inflect in number: *bateaux-mouches*. That's why on Figure 11.4 containing the inflection graph for this MWU, the corresponding boxes contain value assignments for number only. Note that both constituents may or may not agree in gender, here *bateau* is masculine while *mouche* is feminine.

Figure 11.3: Inflection graph *N1* for simple words inflecting like *royal*Figure 11.4: Inflection graph for MWUs inflection like *bateau-mouche*

Unification Variables

An important feature of our formalism are *unification variables*. They are invoked by a dollar sign followed by an identifier which may contain any number of characters, e.g. $\$g1$, $\$num_{10}$, $\$c$, etc. For example, Figure 11.5 shows a graph roughly equivalent¹ to the one on Figure 11.4 in the sense that it allows to generate the same inflected forms for the same MWUs. However, this time, a single path represents both the singular and the plural form. This is possible due to the unification variable $\$n$ which is instantiated in turn to all values of the domain of its category (Nb), here $\$n=s$ then $\$n=p$. When a unification variable occurs in a formula such as $Nb=\$n$, with a single equal sign (=), the system reviews all the values declared in the configuration files for the category (cf. Section 11.2.1). For each value, it makes a new assignment of the variable. The assignment is unique for all occurrences of the variable on a path: if we instantiate the singular value for the first constituent, the same value is set for the third one, as well as for the whole MWU. Similarly, if we instantiate $\$n$ to p while processing the first node, it remains p until the end of the path.

Figure 11.5: Inflection graph for *bateau-mouche* with a unification variable

The inflection graph on Figure 11.5 applies to most kinds of French compounds of types *Noun Noun* and *Noun Adjective* (*bateau-mouche*, *ange gardien*, *circuit séquentiel*, etc.) which are of masculine gender. That is because the output of the final node contains $Gen=m$. For

¹Up to the case when single constituents appearing in the lemma of a MWU are already in the plural, as in *cross-roads*.

all compounds of the same types but of feminine gender, e.g. *main courante*, *moissonneuse-batteuse*, etc., a new graph has to be created which is identical to Figure 11.5 up to the final output containing $\langle Gen=f;Nb=\$n \rangle$. That is not very intuitive since *circuit séquentiel* and *main courante* inflect in the same way, in the sense that in both cases we need to put the first and the last constituent in the plural in order to obtain the plural form of the whole MWU.

That's why another type of instantiation for unification variables has been introduced. It is invoked by a double equal sign ($=$), as opposed to the single equal sign $=$ as for $\$n$ on Figure 11.5. If a unification variable is assigned to a category by this symbol, then the variable is assigned once: it inherits the value of this category from the corresponding constituent, as it appears in the lemma of the MWU. For instance, Figure 11.6 contains a graph describing the inflected forms for both masculine and feminine French compounds of types *Noun Noun* and *Noun Adjective*. Its first box contains the double= $=$ assignment of the gender to variable $\$g$, which means that this variable has its value set to the gender value of the first constituent. For *bateau-mouche* it is set to masculine because *bateau* is masculine, while for *main courante* it is set to feminine.

Figure 11.6: Inflection graph for *bateau-mouche* with two types of instantiation

When a double= $=$ assignment and a single= $=$ assignment occur on the same path for the same variable, the double= $=$ assignment prevails: the variable is instantiated once. For example, on Figure 11.6, the final output contains $Gen=\$g$ but $\$g$ takes the value determined by the first constituent only.

Unification variables are particularly useful in highly inflected languages. For example, in Polish most nouns inflect for number (2 values) and case (7 values), which implies at least 14 different forms (if variants and syncretic forms are distinguished). This score is even higher for adjectives which inflect for number, case and gender (3 till 9 values, according to different approaches). If no unification mechanism were available each of these numerous forms would have to be described by a separate path in the graph. The use of unification variables allows to dramatically reduce the size of the graph (to one path only in most cases).

For example, Figure 11.7 shows the graph for Polish compounds that inflect like *pranie mózgu* (brainwashing) or *powożenie koniem* (horse coaching). Their third constituent has its case fixed (most often to genitive or instrumental). Their first and third constituent inflect in number independently from each other (*pranie mózgów*, *prania mózgu*, *prania mózgów*, etc.). That's why either of them has a different unification variable for number inflection ($\$n1$ and $\$n2$). The three variables $\$n1$, $\$n2$, and $\$c$ may be instantiated to any value from their respective domains ($\{sing,pl\}$, $\{sing,pl\}$, and $\{Nom,Gen,Dat,Acc,Inst,Loc,Voc\}$; cf *Morphology.txt* file in section 11.2.1). The whole MWU inherits its gender, number and case from its first constituent. Its gender is fixed ($Gen==\$g$) while its number and case are instantiated to any of

the 14 possible combinations. The single path in this graph would have to be replaced by 28 different ones if the use of unification variables were not allowed.

Figure 11.7: Inflection graph for *pranie mózgu*

Orthographic and Other Variants

Our formalism allows for any constituent to be omitted or moved within different inflected forms if there is a need for that. It also enables the insertion of extra graphical units which do not appear in the base form of the MWU. This allows to extend an inflection paradigm to a more general variation description, e.g. orthographic or, partly, syntactic variation (see [56] for an extensive study on term variation). For example, in English, *student union* appears in corpus also as *students' union*, and *students' union*, in singular or plural in each case. Our formalism allows to include both types of variation in one description (cf. Figure 11.8).

Figure 11.8: Inflection graph for *student union*

Figure 11.9 shows an example in which, additionally to the insertion of a new constituent, the order of constituents may be reverted. The upper path allows to generate e.g. *birth date* and *birth dates* while the lower one represents the syntactic variants of the previous forms: *date of birth* and *dates of birth*.

Figure 11.9: Inflection graph for *birth date*

Interface with the Morphological System for Simple Words

MULTIFLEX is an implementation of the formalism for the inflectional morphology of MWUs presented above. It supposes the existence of a morphological system for single words which satisfies the following interface constraints:

- For a given sequence of characters it returns its segmentation into indivisible graphical units (tokens) (cf section 11.2.2). For instance, in case of Unitex' definition of a token, sequence *Athens '04* is to be divided into 5 tokens:

"Athens '04" → ("Athens", " ", "'", "0", "4")

- For a given simple inflected form it returns all its possible morphological identifications. A morphological identification has to allow the generation of any other inflected form of the same lemma on demand by the same morphological module. For instance, in case of Unitex, the form *porte* yields 7 morphological identifications (6 of which are factorized with respect to their inflection code):

porte → ((porte,porte.N21:s),(porte,porter.V3:P1s:P3s:S1s:S3s:Y2s))

In case of ambiguity, as above, the proper identification has to be done, for the time being, by the user during the edition of the MWU lemma to be inflected (in future, this task will be partly automated). For instance, in case of *porte-fenêtre* the first constituent has to be identified by the user as a noun rather than a verb.

- For a given morphological identification and a set of inflectional values it returns all corresponding inflected forms. For instance, in Polish, if the instrumental forms of the word *reka* are to be produced, three forms should be returned: *reka* (singular instrumental), *rekami* and *rekoma* (two variants of the plural instrumental).

*(reka,<Case=Inst>) → ((reka,<Nb=sing;Gen=fem;Case=Inst>),
(rekami,<Nb=pl;Gen=fem;Case=Inst>),
(rekoma,<Nb=pl;Gen=fem;Case=Inst>))*

Such definition of an interface between the morphological system for simple words and the one for MWUs allows a better modularity and independence of one another. The latter doesn't need to know how inflected forms of simple words are described, analyzed and generated. It only requires a set of correct inflected forms of a MWU's constituents. Conversely, the former system knows nothing about how the latter one combines the provided forms to produce multi-word sequences.

11.3 Integration in Unitex

One of the major design principles of MULTIFLEX is to be as independent as possible of the morphological system for simple words. However, the existence of such a system is inevitable because MWUs consist of simple words which we need to be able to inflect in order to inflect a MWU as a whole.

In its present version, MULTIFLEX relies on the Unitex simple word inflection system:

- MULTIFLEX uses the same character encoding standards as Unitex, i.e. Unicode 3.0.

- MULTIFLEX uses the Unitex' graph editor for the representation of inflectional paradigms of MWUs.
- MULTIFLEX admits similar principles of the morphological description as those admitted in the DELA system implemented in Unitex. Thus, an inflection paradigm is a set of actions to be performed on the lemma in order to generate its inflected forms, and of corresponding inflection features to be attached to each generated form.
- MULTIFLEX allows to extend the Unitex dictionary treatment to the inflection of a DELAC (DELA electronic dictionary of compounds) into a DELACF (DELA electronic dictionary of compounds' inflected forms). The format of the generated DELACF is compatible with Unitex, while the format of the DELAC is novel but inspired from the one of the DELAS (DELA electronic dictionary of simple words).

The following sections present, for several languages, complete examples of a DELAC into DELACF inflection within the MULTIFLEX/Unitex interface.

11.3.1 Complete Example in English

Let us assume that the description of morphological features of English is given by the following `Morphology.txt` file:

```
English
<CATEGORIES>
Nb:s,p
<CLASSES>
noun:(Nb,<var>)
adj:
```

and that the equivalences between these features and their corresponding codes in DELA dictionaries are given by the following `Equivalences.txt` file:

```
English
s : Nb=s
p : Nb=p
```

Consider the following sample English DELAC file:

```
angle(angle.N1:s) of reflection,NC_NXXXX
Adam's apple(apple.N1:s),NC_XXXXN
air brake(brake.N1:s),NC_XXN
birth date(date.N1:s),NC_NN_NofN
criminal police,NC_XXXinv
cross-roads,NC_XXNs
head(head.N1:s) of government(government.N1:s),NC_NofNs
notary(notary.N3:s) public(public.N1:s),NC_NsNs
rolling stone(stone.N1:s),NC_XXN
student(student.N1:s) union(union.N1:s),NC_Ns'N
```

The corresponding inflection graphs *N1* and *N3* for simple words are represented on figures 11.10 and 11.11 while those for compounds are shown on figures 11.12 through 11.20.

The DELACF dictionary resulting from the inflection, via MULTIFLEX, of the above DELAC is as follows:

angle of reflection,angle of reflection.NC_NXXXX:s
 angles of reflection,angle of reflection.NC_NXXXX:p
 Adam's apple,Adam's apple.NC_XXXXN:s
 Adam's apples,Adam's apple.NC_XXXXN:p
 air brake,air brake.NC_XXN:s
 air brakes,air brake.NC_XXN:p
 date of birth,birth date.NC_NN_NofN:s
 dates of birth,birth date.NC_NN_NofN:p
 birth date,birth date.NC_NN_NofN:s
 birth dates,birth date.NC_NN_NofN:p
 criminal police,criminal police.NC_XXXinv:p
 cross-roads,cross-roads.NC_XXNs:s

11.3.2 Complete Example in French

Let us assume that the description of morphological features of French is given by the following `Morphology.txt` file:

```

French
<CATEGORIES>
Nb : s, p
Gen : m, f
<CLASSES>
noun : (Nb,<var>),(Gen,<var>)
adj:(Nb,<var>),(Gen,<var>)
adv:

```

and that the equivalences between these features and their corresponding codes in DELA

dictionaries are given by the following `Equivalences.txt` file:

```
French
s : Nb=s
p : Nb=p
m : Gen=m
f : Gen=f
```

Consider the following sample French DELAC file (the DELAS inflection codes may vary from those present in UNITEX):

```
avant-garde (garde.N21:fs) , NC_XXN
bateau (bateau.N3:ms) -mouche (mouche.N21:fs) , NC_NN
café (café.N1:ms) au lait , NC_NXXXX
carte (carte.N21:fs) postale (postal.A8:fs) , NC_NN$
cousin (cousin.N8:ms) germain (germain.A8:ms) , NC_NNm f
franc (franc.A47:ms) maçon (maçon.N41:ms) , NC_AN1
mémoire (mémoire.N21:fs) vive (vif.A48:fs) , NC_NN
microscope (microscope.N1:ms) à effet tunnel , NC_NXXXXXXXX
porte-serviette (serviette.N21:fs) , NC_VNm
```

The corresponding inflection graphs for MWUs are shown on figures [11.21](#) through [11.27](#).

The DELACF dictionary resulting from the inflection, via MULTIFLEX, of the above DELAC is as follows:

```
avant-garde , avant-garde.NC_XXN:fs
avant-gardes , avant-garde.NC_XXN:fp
bateau-mouche , bateau-mouche.NC_NN:ms
bateaux-mouches , bateau-mouche.NC_NN:mp
café au lait , café au lait.NC_NXXXX:ms
cafés au lait , café au lait.NC_NXXXX:mp
carte postale , carte postale.NC_NN:fs
cartes postales , carte postale.NC_NN:fp
cousin germain , cousin germain.NC_NNm f:ms
cousins germains , cousin germain.NC_NNm f:mp
cousine germaine , cousin germain.NC_NNm f:fs
cousines germaines , cousin germain.NC_NNm f:fp
franc-maçon , franc maçon.NC_AN1:ms
franc-maçonne , franc maçon.NC_AN1:fs
franc maçon , franc maçon.NC_AN1:ms
franc maçonne , franc maçon.NC_AN1:fs
francs-maçons , franc maçon.NC_AN1:mp
francs-maçonnes , franc maçon.NC_AN1:fp
```

11.3.3 Complete Example in Serbian

Let us assume that the description of morphological features of Serbian is given by the following `Morphology.txt` file:

```

Serbian
<CATEGORIES>
Nb:s,p,w
Case:1,2,3,4,5,6,7
Gen:m,f,n
Anim:v,q,g
Comp:a,b,c
Det:d,k,e
<CLASSES>
noun:(Nb,<var>),(Case,<var>),(Gen,<var>),(Anim,<fixed>)
adj:(Nb,<var>),(Case,<var>),(Gen,<var>),(Anim,<var>),(Comp,<var>),(Det,<var>)
adv:

```

The peculiarity of this morphological model is not only its reachness but also the existence of *no-care* features like *Anim=g* or *Det=e*. These features agree with all other features in the same category. They are used only for some particular subclasses of nouns or adjectives and are necessary for a better compactness of the inflection paradigms of simple words which are already considerably huge, and would be even larger if no *no-care* symbols were used.

Let us assume that the equivalences between the above features and their corresponding

codes in DELA dictionaries are given by the following `Equivalences.txt` file:

```
Serbian
s:Nb=s
p:Nb=p
w:Nb=w
1:Case=1
2:Case=2
3:Case=3
4:Case=4
5:Case=5
6:Case=6
7:Case=7
m:Gen=m
f:Gen=f
n:Gen=n
v:Anim=v
q:Anim=q
g:Anim=g
a:Comp=a
b:Comp=b
c:Comp=c
d:Det=d
k:Det=k
e:Det=e
```

Consider the following sample Serbian DELAC file (the DELAS inflection codes may vary from those present in Unitex):

```
zxiro racyun(racyun.N1:ms1q),NC_2XN1+N+Comp
avio-prevoznik(prevoznik.N10:ms1v),NC_2XN2+N+Comp
predsednik(predsednik.N10:ms1v) drzxave(drzxava.N600:fs2q),NC_N2X1+N+Comp

Chapter 12

Cascade of Transducers

This chapter presents the tool *CasSys* that provides users the possibility to create Unitex cascade of transducers and new opportunities to work on natural language with Finite State Graphs. A *cascade of transducers* applies several FSGraphs (also called automata or transducers), one after the other, onto a text: each graph modifies the text, and changes can be useful for further processings with the next graphs. Such a system is typically used for syntactic analysis, chunking, information extraction, recognizing named entities etc. To do that, CasSys uses a succession of "locate patterns" to which was added special options and behaviors.

The first prototype of the *CasSys* system was created in 2002 at the LI (Computer science Laboratory of Université François Rabelais Tours, France) [31]. This prototype was totally dedicated to named entity recognition. Later, CasSys was generalized to allow any sort of work needing a cascade: throughout the years, it was improved but never really integrated in Unitex, until a recent project which resulted in the complete integration of CasSys in Unitex¹.

Unitex grammars are known as Context free grammars and contain the notion of transduction derived from the field of finite state automata. A grammar with transduction (a transducer) is enabled to produce some output. CasSys is dedicated to the application of transducers in the form of a cascade.

A cascade can be used for syntactic analysis, chunking, information extraction, etc. Transducers are interesting because they allow the association of a recognized sequence to informations found in the outputs of the graphs. These outputs can:

- Be merged with the recognized sequence and appear in the resulting concordance or modified text.
- Replace the recognized sequence to modify the text.

These two operations transform the text or add information inside the text.

¹"Feder-Région Centre Entités nommées et nommables" managed by Denis Maurel, LI, Tours, France, integration carried out by Nathalie Friburger and David Nott

In this chapter, we will explain how to create/modify cascades of transducers and how to apply them. Then, we deal with options and behaviors offered by CasSys.

12.1 Applying a cascade of transducers with CasSys

Applying a cascade of transducers consists in the modelling of linguistic phenomena in several transducers listed in a specific order to apply on a text: CasSys and its interface into Unitex permits to do this. This section explains how to use the interface to create, manage (order, add, delete) graphs and apply the cascade.

12.1.1 Creating the list of transducers

In order to manage the list of transducers, the menu FSGraph proposes two submenus: "*New cascade*" and "*Edit cascade...*" (Figure 12.1). You can choose "*new cascade*" to create a new list of transducers. If you want to modify an existing cascade, you can choose "*Edit cascade*" that open a file explorer to choose the cascade to open.

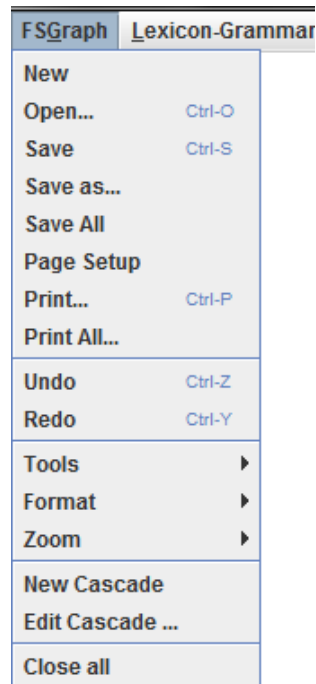

Figure 12.1: "FSGraph" menu of Unitex and submenus "*New cascade*" and "*Edit cascade...*"

In the language directory, there is a directory named CasSys where the cascade configuration files are stored. Those files are text files with the extension *.csc* (ex: mycascade.csc).

12.1.2 Editing the list of transducers

The CasSys configuration window (Figure 12.2) is divided into three parts :

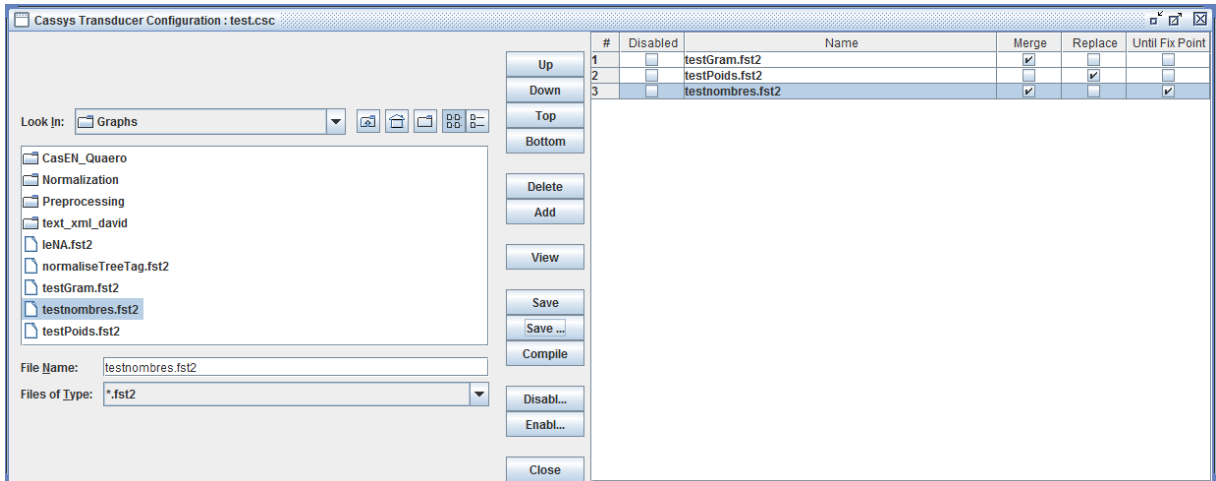

Figure 12.2: CasSys configuration window with a list of transducers on the right hand side

1. a *file explorer* at the left of the frame permits to select the transducers to place in the cascade. The file explorer only displays *fst2* files (all the graphs you want to place in the list of transducers must be compiled in *fst2* format).

To edit the cascade, select the graphs in the file explorer at the left and drag and drop them into the right frame of the window.

2. A *table* at the right displays the cascade: the ordered list of transducers and the selected options for each graph. This table is obviously empty for a new cascade.

The different columns of this table (Figure 12.3) show the numbering of each graph and permit to choose its behavior:

- **#**: Rank of the graph/transducer in the cascade. The resulting file of a graph is numbered with this rank.
- **Disabled**: checkbox to disable the current graph. *Disabled* meaning "not applied in the cascade". The disabled graphs appear not numbered, in light grey and striked out.
- **Name**: The name of the graph (with extension *fst2*). If you let the mouse over the name of the graph, a tooltip appears with the whole path of the graph. Graphs which source file are not found appear in italic red font style.
- **Merge**: Whether the transducer should be applied in merge mode at the sense of *unitex locate* pattern.
- **Replace**: Whether the transducer should be applied in replace mode at the sense of *unitex locate* pattern.
- **Until fix point**: Whether the transducer should be applied once or re-applied several times until no change occur in the text i.e. until a fix point is reached (See 12.2.2).

3. Several buttons in the middle for different needs:

- "Up/Down/Top/Bottom" buttons are used to modify the order of the transducers on the list (it moves the selected transducer in the list); "Up" and "Down" to move the selected transducer one line up or down, and "Top" and "Bottom" to move the selection to the top or to the end of the list.
- "Delete" permits to remove a selected transducer from the list of transducers.
- "Add" adds a transducer (previously selected in the explorer) onto the list. It replaces the drag and drop actions described above.
- "View" opens the selected graph either in the file explorer or in the list of transducers of the window. It is very useful to get a quick access to any transducer either to take a quick look at its content or to modify it.
- "Save" and "Save as" permit to save the list of transducers. By default, the lists of transducers are stored in the CasSys directory of the current language (e.g. English/CasSys).
- "Compile" recompile all the graphs of the cascade. Very useful to avoid to recompile a graph after changes.
- "Disable all" to disable all the graphs of the cascade.
- "Enable all" to enable all the graphs of the cascade.
- "Close" to close the current window.

#	Disabled	Name	Merge	Replace	Iter

Figure 12.3: The table/list of transducers

12.1.3 Applying a cascade

To apply a cascade on a text, you can select the menu "Text / Apply CasSys cascade..." (Figure 12.4) which will open the CasSys window. This submenu "Apply CasSys cascade..." is active only if a text has previously been opened.

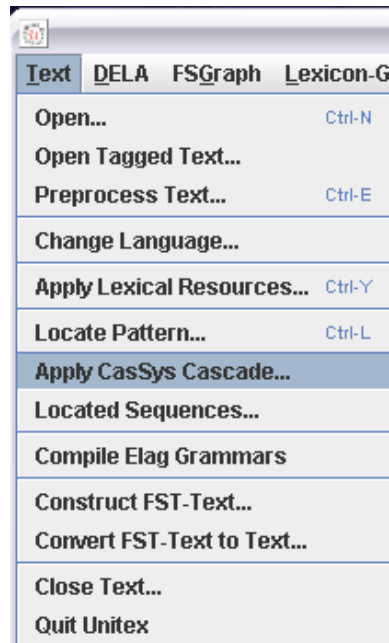

Figure 12.4: "Text" menu of Unitex and submenu "Apply CasSys Cascade..."

The CasSys window (Figure 12.5) displays the content of the CasSys directory of the current language. It allows you to choose the cascade file to be applied on the text. When this list is chosen, you can click on the "Launch" button to apply the cascade.

Figure 12.5: CasSys Window to launch a cascade of transducers

All morphological-mode dictionaries added in your preferences are applied to your graphs. Preferences may be edited from the main Unitex frame (*info / Preferences / morphological-mode dictionaries*).

12.1.4 Sharing a cascade transducer list file

In order to ease collaborating work within CasSys, a simple export/import system for the cascades is provided. This possibility is offered in the "Text / Apply CasSys cascade..." menu (Figure 12.5).

To share a cascade list file, the following steps has to be fulfilled :

1. **Export** : Select a cascade file and click the export button. (A ready to share file is created in the /CasSys/Share repository)
2. Send the file to share to your colleague
3. **Import** : Select the imported file and click the import button. (A ready to use file is created in the /CasSys repository)

12.2 Details on the behavior of CasSys

In this section , we present details concerning the functioning of CasSys.

12.2.1 Type of graphs used

CasSys uses the compiled version of the graphs (the `fst2` files). CasSys can handle the local grammars (section 6.1.4) presented in Chapter 6. The grammars used in the cascade must follow the constraints of the grammars used in Unitex. They may use subgraphs, morphological filters, the morphological mode, and references to information in dictionaries.

CasSys does not support debug-mode `fst2` files (6.10.7). When you apply a graph in debug mode through the `Text > Locate Pattern` menu, the system compiles the graph into a special debug-mode format. To obtain a regular `fst2` file, compile the graph again, either with the `FSGraph` menu, or with a command line, or by unchecking the debug mode before applying the graph with `Text > Locate Pattern` menu.

12.2.2 Repeat until fix point behaviour

CasSys may apply a transducer on a text while concordances are found. This behavior is selected if the checkbox **Until fix point** is checked or not for each graph of a cascade. This section presents the behaviour of this option. For instance, consider the very simple graph

12.6 which recognizes AB and replaces it with A .

Figure 12.6: Transducer which modifies BA in A

Consider the text *B B B A A A*. Applying the graph 12.6 onto this text with the option *Until fix point* will have the following result :

initial text	B	B	B	A	A	A	
iteration 1		B	B	A	A	A	1 match
iteration 2			B	A	A	A	1 match
iteration 3				A	A	A	1 match
iteration 4				A	A	A	0 match

During the three first iterations, a match is found, so the graph re-applied on the resulting text. At the fourth iteration, no match is found, the graph is not re-applied.

Warning: Be aware of the risk of livelock when applying this option. For example, a transducer which recognizes *A* and replaces it with *A* would be caught in a livelock if applied on the example text.

12.2.3 The Unitex rules used for the cascade

In the cascade, each successive graph is applied following the unitex rules:

- *Insertion to the left of the matched patterns:* in the merge mode, the output is inserted to the left of the recognized sequence.
- *Priority of the leftmost match:* during the application of a local grammar, overlapping occurrences are all indexed. During the construction of a concordance, all these overlapping occurrences are presented but CasSys modifies the text with each graph of the cascade : so it is necessary to choose among these occurrences the one that will be taken into account. To do that, the priority is given to the leftmost sequence.
- *Priority of the longest match:* in CasSys, during the application of a graph, it is the longest sequence that will be kept.
- *Search limitation to a certain number of occurrences:* in CasSys, this search is not limited. Such a limitation has no sense in the use of CasSys, we always index all occurrences in the text.

12.2.4 A special way to mark up patterns with CasSys

The output of the transducers can be used to insert special information into texts, particularly to mark up the recognized patterns: it is possible to use all the marks you want such as (), [], "", etc. or xml tags such as <xxx> </xxx>.

CasSys also offers a *special way to mark up patterns*, that offers some advantages and that we present here.

Unitex splits texts into different sorts of tokens like the sentence delimiter S; the stop marker STOP, contiguous sequences of letters, lexical tags aujourd'hui, .ADV,

etc. The lexical tag is used by CasSys in a special way. The lexical tag (between curly brackets) is normally used to avoid ambiguities (see section 2.5.4 and section 7.5.1). For example, if the token *{curly brackets,.N}* is in a text, neither "curly" nor "brackets" will be recognized but the whole sequence "curly brackets" or the tag <N>. A lexical tag can contain complex lexical information. For example, the codes *N+Pers+Hum:fs* tags a token which is a noun, a person, a human and feminine singular. In a graph, you can look for a lexical token using the lexical codes it contains: for example, you can write lexical masks such as <N> to search a noun, <Pers+Hum> for a human person or simply <Pers> (lexical masks are explained in section 4.3.1).

In CasSys, we use the lexical tag in a special way. A cascade of transducers is interesting to locate the island of certainty first. It is necessary for such a system to avoid that previously recognized patterns be ambiguous with patterns recognized by the following graphs. To do that, you can tag the patterns of your graphs surrounding them by *{* and *,.tag1+tag2+tagn}* in the outputs of the graph (where *tag1, tag2, etc.* are your own tags).

To explain this behavior, here is a very simple example. The text on which we work is :

bac a b c cc a b b ba ab a b bca a b c abaabc.

The graph *grfAB* (12.7) recognizes the sequence *a b* in the text and tags this sequence with the lexical tag *{a b,.AB}*. The results are merged with the text adding the outputs *{* and *,.AB}* around "a b" sequences.

Figure 12.7: The graph *grfAB*

The resulting text is : *bac {a b,.AB} c cc {a b,.AB} b ba ab {a b,.AB} bca {a b,.AB} c abaabc.*

Now the pattern *a b* is tagged *AB*. A part (a or b alone) of this pattern cannot be recognized because of the tagging of *a b*.

After that graph, the cascade applies another graph named *tagAB* (12.8). It has two paths:

- the first one to recognize the lexical mask <AB> followed by *c* and tags this sequence as *ABC*.
- the second one to recognize and tag *bca* preceded by <AB>. Only *bca* is tagged as *BCA*.

Figure 12.8: The graph tagAB

The resulting text is : `bac {{a b,..AB} c,..ABC} cc {a b,..AB} b ba ab {a b,..AB} {bca,..BCA} {{a b,..AB} c,..ABC} abaabc.`

The concordance displayed by Unitex should be like in (12.9). //

Note that for programming reasons (ambiguities between characters in the curly brackets of the lexical tags), we have no option but to place backslashes \ before all ambiguous characters for Unitex ; that is why these symbols are protected with \ in the concordance to avoid problems in Unitex.

Figure 12.9: The concordance resulting from this cascade

12.3 Generic Graphs

Sometimes, we are able to locate elements because of their context, but if these elements appear without context, then they cannot be identified. In order to locate such occurrences, CasSys proposes to utilise generic graphs. These graphs contain empty boxes that are filled automatically by the program before being applied to the text. These generic graphs work only with the usage of curly brackets, because the program consults the token list of the text to be analysed by the future graph.

12.3.1 Identifying a Generic Graph

CasSys recognises a graph as generic graph if the column *Generic* is checked (figure 12.10).

#	Disabled	Name	Merge	Replace	Until Fix Point	Generic
1	<input type="checkbox"/>	generic.fst2	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
2	<input type="checkbox"/>	y.fst2	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
3	<input type="checkbox"/>	x.fst2	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

Figure 12.10: Generic Graph

12.3.2 Structure of a Generic Graph

A path in a generic graph must begin with a box containing \$G and an opening curly bracket as output. It is this box which is updated by CasSys. The second box has as output the element to be searched. In the figure 12.11, CasSys places in the box all the entries of category x extracted from the token list (tok_by_alph.txt) of the text. For example, CasSys extracts A from the line $\{A,.x\}$ of the token list of the text as shown in the figure 12.12. Additionally, a negative right context (section 6.3 is added to prevent the element from being annotated twice.

Figure 12.11: Generic Graph

Figure 12.12: Modified Generic Graph

In the case of a token list entry $\{\{A,.y\}\{B,.z\},.x\}$ the graph of the figure 12.11 places in the box $A B$ as displayed in the figure 12.13.

Figure 12.13: Modified Generic Graph

Some restrictions are possible by putting in the second box a category, such as y in the figure 12.14; as a result only A is placed in the box as in the figure 12.15.

On the other hand, the negation of a category, for example $\sim y$ in the figure 12.16 will put B in this box (figure 12.17).

If the output of the graph needs to be complemented with certain information that need not be searched, a third box can be added as in the figure 12.18.

Figure 12.14: Generic Graph with a restriction

Figure 12.15: Modified Generic Graph

Figure 12.16: Generic Graph with a negation

Figure 12.17: Modified Generic Graph

Figure 12.18: Generic Graph with Additional Information

12.4 The results of a cascade

12.4.1 Displaying the concordance of a cascade

The results of a cascade are stored in an index file (*concord.ind*), just as for the "Locate pattern" operation. This index file contains all the sequences recognized using the restrictions imposed by the rules of unitex.

In order to display a concordance, you have to access the frame "Text / Located sequences..." and click on the "Build concordance" button (as described in Chapter 6). The figure 12.19 presents a sample of concordance resulting of a cascade recognizing named entities.

12.4.2 The different resulting files of a cascade

CasSys keeps all the text created by each graph of the cascade. This can be useful to test, debug or check the different results of the cascade. It is possible to correct the

ieux sergent se mit à leur tête. " Merci, / capitaine..N+Entity+Function+Military/ ! dit Mr. Fogg : " Savez-vous une chose, ajouta-t-il, / capitaine..N+Entity+Function+Military/ ?... - Fogg. que ainsi conçue : Suez à Londres. Figure 12.19: Concordance of CasSys under Unitex

errors on the order of the graphs or to find the errors in the writing of the graphs. A good idea is to write the name of the graph recognizing a pattern in the output of this graph: thanks to that, you can see in the final results the name of the graph by which a pattern is recognized.

If you apply a cascade on the text named `example.txt`, two directories are created: `example_snt` and `example_csc`. The files produced in `example_csc` are the results obtained by each graphs. These files are named according to the number of the graph which produced them. For example, if the third graph of a cascade finds at least a pattern, the results of this graph will be stored in the directory `example_3_0_snt` and the file named `example_3_0.snt` will contain the modified text.

12.4.3 An xml-like output text for lexical tags

The output is provided in two forms: the direct output of the transducers, and an XML-like output with the lexical tags transformed into XML. This change is done in order to provide the end user with more easily manageable text. From this format, it is possible to use one of the numerous tools to process xml and it is easier to apply further transducers to get the desired output.

The direct output of the transducers is in the `example_csc.raw` file. The xml-ized output text is copied in the `example_csc.txt` file.

More precisely, lexical tags have the following format :

```
{forme.lemme,code1+code2:flex1:flex2}
```

The corresponding xml-like output of CasSys has the following format :

```
<csc>
  <form>forme</form>
  <lem>lemme</lem>
  <code>code1</code>
  <code>code2</code>
  <inflect>flex1</inflect>
  <inflect>flex2</inflect>
</csc>
```

The DTD of our xml format is:

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<!ELEMENT text (#PCDATA|csc)*>
<!ELEMENT csc (form,lem?,code*,inflect*) >
<!ELEMENT form (#PCDATA|csc)*>
<!ELEMENT lem (#PCDATA)>
<!ELEMENT code (#PCDATA)>
<!ELEMENT inflect (#PCDATA)>
```

Chapter 13

Use of external programs

This chapter presents the use of the different programs of which Unitex is composed. These programs, which can be found in the `Unitex/App` directory, are automatically called by the interface (in fact, `UnitexToolLogger` is actually called, in order to reduce significantly the size of the downloadable zip file). It is possible to see the commands that have been executed by clicking on "Info>Console". It is also possible to see the options of the different programs on "Info>Help on commands" (see Figure 13.1). Note that that all Unitex programs support the `-h/--help` option.

Figure 13.1: Help on commands

WARNING: many programs use the text directory (`my_text_snt`). This directory is created by the graphical interface after the normalization of the text. If you work with the command line, you have to create the directory manually before the execution of the program `Normalize`.

WARNING (2): whenever a parameter contains spaces, it needs to be enclosed in quotation marks so it will not be considered as multiple parameters.

WARNING (3): many programs need an `Alphabet.txt` file. For all those programs, this information can be omitted. In that case, a default definition of letters is used (see `u_is_letter` in `Unicode.cpp` source file).

13.1 Creating log files

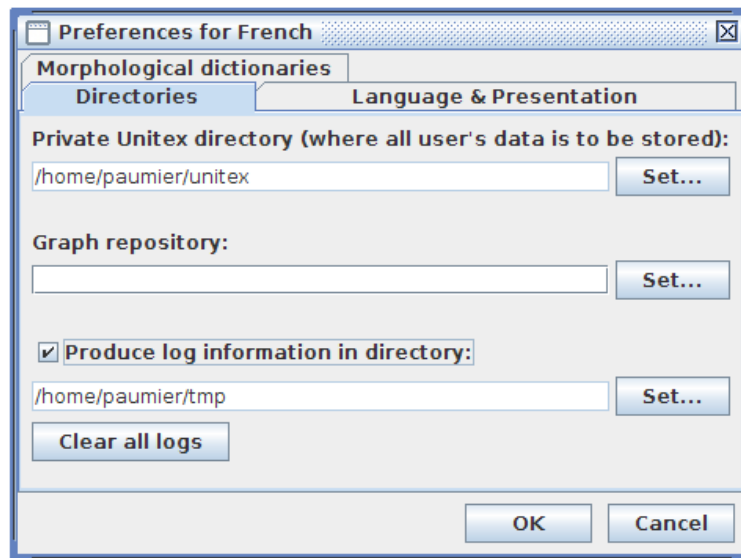

Figure 13.2: Logging configuration

You can create log files of external program launches. These log files can be useful for debugging or regression tests. You just need to enable this feature in the Preferences frame. You have to choose a log directory where all log files will be stored and to select the "Produce log" check box. Clicking on the "Clear all logs" button will remove all log files contained in this directory, if any. Then, any further program execution will produce a `unitex_log_XXX.ulp` file located in the log directory. XXX stands for the log number that can be found in the console (see next section).

13.2 The console

When Unitex launches an external program, the invoked command line is stored in the console. To see it, click on "Info>Console". When a command emits no error

message, it is displayed with a green icon. Otherwise, the icon is a red triangle that you can click on to see the error messages, as shown on Figure 13.3. This is useful when an error message occurs so fast that you cannot read it. If a command has been logged, its log number appears in the second column. Note that you can export all the commands displayed in the console to the clipboard with Ctrl+C.

Figure 13.3: Console

13.3 Unitex JNI

You can use Unitex as a Java Native interface by including the following imports :

```
import fr.umlv.unitex.jni.UnitexJni;
import java.io.*;
import fr.umlv.unitex.*;
```

This will allow you to load .bin, .fst2 and alphabet files and to keep them in memory persistently. You use the filename created by loadPersistent* function.

```
String persistentAlphabet = UnitexJni.loadPersistentAlphabet("/.../unitex/Alphabet/");
String persistentFst2 = UnitexJni.loadPersistentFst2("/.../unitex/French/");
String persistentDictionary = UnitexJni.loadPersistentDictionary(
"/.../unitex/French/Dela/communesFR+.bin");
```

13.4 Text file encoding parameters

Unitex uses Unicode for text file14.1. All program which read or write text file share same encoding parameters. Possible format are utf16le-bom, utf16le-no-bom,

utf16be-bom, utf16be-no-bom, utf8-bom, utf8-no-bom, for Unicode Big-Endian, Little-Endian and UTF-8, with or without Unicode byte order mark at the beginning of the file. For the input format, you can specify several *-bom encoding separated by comma, but only one *-no-bom encoding.

OPTIONS:

- `-k=ENCODING/--input_encoding=ENCODING`: input text file format. Can contain several value, separated by a comma;
- `-q=ENCODING/--output_encoding=ENCODING`: output text file format.

By default, value are `--input_encoding=utf16le-bom, utf16be-bom, utf8-bom --ou`

13.5 BuildKRMwuDic

`BuildKRMwuDic [OPTIONS] dic`

This program generates a MWU dictionary graph from a text table `dic` describing each component of each MWU.

OPTIONS:

- `-o GRF/--output=GRF`: .grf file to produce;
- `-d DIR/--directory=DIR`: inflection directory containing the inflection graphs required to produce morphological variants of roots;
- `-a ALPH/--alphabet=ALPH`: alphabet file to use;
- `-b BIN/--binary=BIN`: .bin simple word dictionary to use.

13.6 CasSys

`Cassys [OPTIONS] <snt>`

This program applies an ordered list of grammars to a text and constructs an index of the occurrences found.

OPTIONS:

- `-a ALPH/--alphabet=ALPH`: the language alphabet file
- `-r X/--transducer_dir=X`: take transducer on directory X (so you don't specify full path for each transducer; note that X must be (back)slash terminated

- `-l TRANSDUCERS_LIST/--transducers_list=TRANSDUCERS_LIST`: the transducers list file with their output policy
- `-s transducer.fst2/--transducer_file=transducer.fst2`: a transducer to apply
- `-m output_policy/--transducer_policy=output_policy`: the output policy of the transducer specified
- `-t TXT/--text=TXT`: the text file to be modified, with extension `.snt`;
- `-i/--in_place`: mean uses the same `csc/snt` directories for each transducer
- `-d/--no_create_directory`: mean the all `snt/csc` directories already exist and don't need to be created
- `-g minus/--negation_operator=minus`: uses minus as negation operator for Unitex 2.0 graphs
- `-g tilde/--negation_operator=tilde`: uses tilde as negation operator (default)
- `-h/--help`: display this help

CasSys applies a list of grammar to a text and saves the matching sequence index in a file named `concord.ind` stored in the text directory. The target text file has to be a preprocessed `snt` file with its `_snt/` directory. The transducer list file is a file in which each line contains the path to a transducer followed by the output policy to be applied to this transducer.

Instead a list file, you can specify each file and each output policy by a set of couple of `-s/--transducer_file` and `-m/--transducer_policy` argument to enumerate the list

The policy may be `MERGE` or `REPLACE`.

The file option, the alphabet option and the transducer list file option are mandatory

As the locate pattern program, this program saves the references to the found occurrences in a file called `concord.ind` stored in the `_snt` directory of the text. The file `concord.ind` produced is in the same format as described in the chapter 14, but the cascade may be constituted of graphs applied in merge or replace mode so the `#M` or `#R` at the first line of the file `concord.ind` has no sense in this context.

13.7 CheckDic

CheckDic [OPTIONS] dic

This program carries out the verification of the format of a dictionary of DELAS or DELAF type. `dic` corresponds to the name of the dictionary that is to be verified.

OPTIONS:

- `-f/--delaf`: checks an inflected dictionary;
- `-s/--delas`: checks a non inflected dictionary;
- `-r/--strict`: strict syntax checking against unprotected dot and comma;
- `-t/--tolerate`: tolerates unprotected dot and comma (default);
- `-n/--no_space_warning`: tolerates spaces in grammatical/semantic/inflectional codes;
- `-p/--skip_path`: does not display the full path of the dictionary (useful for consistent log files across several systems);
- `-a ALPH/--alphabet=ALPH`: specifies the alphabet file to use.

The program checks the syntax of the lines of the dictionary. It also creates a list of all characters occurring in the inflected and canonical forms of words in the text, the list of grammatical codes and syntax, as well as the list of inflection codes used. The results of the verification are stored in a file called `CHECK_DIC.TXT`.

Selecting strict syntax checking detects using unprotected dot in inflected form, or unprotected comma in lemma. The `--tolerate` option acts like Unitex 2.0 and lower and does not detect them.

13.8 Compress

Compress [OPTIONS] dictionary

OPTIONS:

- `-o BIN/--output=BIN`: sets the output file. By default, a file `xxx.dic` will produce a file `xxx.bin`;
- `-f/--flip`: indicates that the inflected and canonical forms should be swapped in the compressed dictionary. This option is used to construct an inverse dictionary which is necessary for the program `Reconstruca`o;

- `-s/--semitic`: indicates that the semitic compression algorithm should be used. Setting this option with semitic languages like Arabic significantly reduces the size of the output dictionary.
- `--v1`: produces an old style .bin file
- `--v2`: produces a new style .bin file, with no file size limitation to 16 Mb and a smaller size (default)

This program takes a DELAF dictionary as a parameter and compresses it. The compression of a dictionary `dico.dic` produces two files:

- `dico.bin`: a binary file containing the minimum automaton of the inflected forms of the dictionary;
- `dico.inf`: a text file containing the compressed forms required for the reconstruction of the dictionary lines from the inflected forms contained in the automaton.

For more details on the format of these files, see chapter [14](#).

13.9 Concord

```
Concord [OPTIONS] <index>
```

This program takes a concordance index file produced by the program `Locate` and produces a concordance. It is also possible to produce a modified text version taking into account the transducer outputs associated to the occurrences. Here is the description of the parameters:

OPTIONS:

- `-f FONT/--font=FONT`: the name of the font to use if the output is an HTML file;
- `-s N/--fontsize=N`: the font size to use if the output is an HTML file. The font parameters are required if the output is an HTML file;
- `--only_ambiguous`: Only displays identical occurrences with ambiguous outputs, in text order.
- `--only_matches`: this option will force empty right and left contexts. Moreover, if used with `-t/--text`, Concord will not surround matches with tabulations
- `-l X/--left=X`: number of characters on the left of the occurrences (default=0). In Thai mode, this means the number of non-diacritic characters.

- `-r X/--right=X`: number of characters (non-diacritic ones in Thai mode) on the right of the occurrences (default=0). If the occurrence is shorter than this value, the concordance line is completed up to `right`. If the occurrence is longer than the length defined by `right`, it is nevertheless saved as whole.

NOTE: For both `--left` and `--right`, you can add the `s` character to stop at the first `{S}` tag. For instance, if you set `40s` for the left value, the left context will end at 40 characters at most, less if the `{S}` tag is found before.

Sort order options:

- `--TO`: order in which the occurrences appear in the text (default);
- `--LC`: left context for primary sort, then occurrence for secondary sort;
- `--LR`: left context, then right context;
- `--CL`: occurrence, then left context;
- `--CR`: occurrence, then right context;
- `--RL`: right context, then left context;
- `--RC`: left context, then occurrence.

For details on the sorting modes, see section [4.8.2](#).

Output options:

- `-H/--html`: produces a concordance in HTML format encoded in UTF-8 (default);
- `-t/--text`: produces a concordance in Unicode text format;
- `-g SCRIPT/--glossanet=SCRIPT`: produces a concordance for GlossaNet in HTML format. The HTML file is encoded in UTF-8;
- `-p SCRIPT/--script=SCRIPT`: produces a HTML concordance file where occurrences are links described by `SCRIPT`. For instance, if you use `-phttp://www.google.com/search?q=`, you will obtain a HTML concordance file where occurrences are hyperlinks to Google queries;
- `-i/--index`: produces an index of the concordance, made of the content of the occurrences (with the grammar outputs, if any), preceded by the positions of the occurrences in the text file given in characters;
- `-u offsets/--uima=offsets`: produces an index of the concordance relative to the original text file, before any Unitex operation. `Offsets` is supposed to be the file produced by `Tokenize's --output_offsets` option

- `--PRLG=X, Y`: produces a concordance for PRLG corpora where each line is prefixed by information extracted with Unxmlize's `--PRLG` option. `X` is the file produced by Unxmlize's `--PRLG` option and `Y` is the file produced by Tokenize's `--output_offsets` option. Note that if this option is used in addition with `-u`, the `Y` argument overrides the argument of `-u`;
- `-e/--xml`: produces xml index of the concordance;
- `-w/--xml-with-header`: produces xml index of the concordance with full xml header;
- `-A/--axis`: quite the same as `--index`, but the numbers represent the median character of each occurrence. For more information, see [32];
- `-x/--xalign`: another index file, used by the text alignment module. Each line is made of 3 integers `X Y Z` followed by the content of the occurrence. `X` is the sentence number, starting from 1. `Y` and `Z` are the starting and ending positions of the occurrence in the sentence, given in characters;
- `-m TXT/--merge=TXT`: indicates to the program that it is supposed to produce a modified version of the text and save it in a file named `TXT` (see section 6.10.4).

Other options:

- `-d DIR/--directory=DIR`: indicates to the program that it must not work in the same directory than `<index>` but in `DIR`;
- `-a ALPH/--alphabet=ALPH`: alphabet file used for sorting;
- `-T/--thai`: option to use for Thai concordances.

The result of the application of this program is a file called `concord.txt` if the concordance was constructed in text mode, a file called `concord.html` if the output mode was `--html`, `--glossanet` or `--script`, and a text file with the name defined by the user of the program if the program has constructed a modified version of the text.

In `--html` mode, the occurrence is coded as a hypertext link. The reference associated to this link is of the form ``. `X` et `Y` represent the beginning and ending positions of the occurrence in characters in the file `text_name.snt`. `Z` represents the number of the sentence in which the occurrence was found.

13.10 ConcorDiff

ConcorDiff [OPTIONS] <concor1> <concor2>

This program takes two concordance files and produces an HTML page that shows their differences (see section 6.10.6, page 157). <concor1> and <concor2> concordance index files must have absolute names, because Unitex uses these names to deduce on which text there were computed.

OPTIONS:

- -o X/--out=X: output HTML page;
- -f FONT/--font=FONT: name of the font to use in output HTML page;
- -s N/--size=N: font size to use in output HTML page.
- -d/--diff_only: don't show identical sequences;

13.11 Convert

Convert [OPTIONS] <text_1> [<text_2> <text_3> ...]

With this program you can transcode text files.

OPTIONS:

- -s X/--src=X: input encoding;
- -d X/--dest=X: output encoding (default=LITTLE-ENDIAN);

Transliteration options (only for Arabic):

- -F/--delaf: the input is a DELAF and we only want to transliterate the inflected form and the lemma;
- -S/--delas: the input is a DELAS and we only want to transliterate the lemma.

Output options:

- -r/--replace: input files are overwritten (default);
- -o file/--output=file: name of destination file (only one file to convert);
- --ps=PFX: input files are renamed with the PFX prefix (toto.txt ⇒ PFXtoto.txt);
- --pd=PFX: output files are renamed with the PFX prefix;

- `--ss=SFX`: input files are named with the SFX suffix; (`toto.txt` \Rightarrow `totoSFX.txt`);
- `--sd=SFX`: output files are named with the SFX suffix.

HTML options:

`Convert` offers some special options dedicated to HTML files. You can use a combination of the following options:

- `--dnc` (Decode Normal Chars): things like `é`; `x`; and `ø` will be decoded as the single equivalent unicode character, except if it represents an HTML control character;
- `--dcc` (Decode Control Chars): `<`; `>`; `&`; and `"`; will be decoded as `<` `>` `&` and the quote (the same for their decimal and hexadecimal representations);
- `--eac` (Encode All Chars): every character that is not supported by the output encoding will be encoded as a string like `ǉ`;
- `--ecc` (Encode Control Chars): `<` `>` `&` and the quote will be encoded by `<`; `>`; `&`; and `"`;

All HTML options are deactivated by default.

Other options:

- `-m/--main-names`: prints the list of the encoding main names;
- `-a/--aliases`: prints the list of the encoding aliases;
- `-A/--all-infos`: prints all the information about all the encodings;
- `-i X/--info=X`: prints all the information about the encoding X.

The encodings can take values in the following list (non exhaustive, see below):

13.12 Dico

```
Dico [OPTIONS] <dic_1> [<dic_2> <dic_3>...]
```

This program applies dictionaries to a text. The text must have been cut up into lexical units by the `Tokenize` program.

OPTIONS:

- `-t TXT/--text=TXT`: complete `.snt` text file name;
- `-a ALPH/--alphabet=ALPH`: the alphabet file to use;
- `-m DICS/--morpho=DICS`: this optional parameter indicates which morphological-mode dictionaries are to be used, if needed by some `.fst2` dictionaries. `DICS` represents a list of `.bin` files (with full paths) separated with semi-colons;
- `-K/--korean`: tells `Dico` that it works on Korean;
- `-s/--semitic`: tells `Dico` that it works on a semitic language (needed if `Dico` has to compress a dictionary);
- `-u X/--arabic_rules=X`: specifies the Arabic typographic rule configuration file.

- `r X/--raw=X`: indicates that Dico should just produce one output file `X` containing both simple and compound words, without requiring a text directory. If `X` is omitted, results are displayed on the standard output.

`<dic_i>` represents the path and name of a dictionary. The dictionary must be a `.bin` dictionary (obtained with the `Compress` program) or a dictionary graph in the `.fst2` format (see section 3.8, page 68). It is possible to give priorities to the dictionaries. For details see section 3.8.1.

The program `Dico` produces the following files, and saves them in the directory of the text:

- `dlf`: dictionary of simple words in the text;
- `dlc`: dictionary of compound words in the text;
- `err`: list of unknown words in the text;
- `tags_err`: unrecognized simple words that are not matched by the `tags.ind` file;
- `tags.ind`: sequences to be inserted in the text automaton (see section 3.8.3, page 69);
- `stat_dic.n`: file containing the number of simple words, the number of compound words, and the number of unknown words in the text.

NOTE: Files `dlf`, `dlc`, `err` and `tags_err` are not sorted. Use the program `SortTxt` to sort them.

13.13 DumpOffsets

Usage: `DumpOffsets [OPTIONS] <txt>`

`<txt>`: an offset file to read

`DumpOffsets` dump sequence offset to study them.

OPTIONS:

- `-o X/--old=X`: name of old file to read
- `-n X/--new=X`: name of new file to read
- `-p X/--output=X`: name of output dump file to write

- `-f/--full`: dump common text additionally
- `-q/--quiet`: display no message
- `-c/--no_escape_sequence`: don't escape text sequence
- `-h/--help`: this help

Example:

```
UnitexToolLogger Normalize -r .\resource\Norm.txt
    .\work\text_file.txt
    --output_offsets .\work\text_file_offset.txt
UnitexToolLogger DumpOffsets -o .\work\text_file_offset.txt
    -n .\work\text_file_offset.snt
    -p .\work\dump\dump_offsets.txt .\work\text_file_offset.txt
```

Other Usage: `DumpOffsets [-m/--merge] [OPTIONS] <txt>`

<txt>: an offset file to read

Merge two offset file(14.13.10, page 337)) produced by two successive modification of text

OPTIONS:

- `-o X/--old=X`: name of old file to read
- `-n X/--output=X`: name of output merged offset file to write

Other Usage: `DumpOffsets [-v/--convert_modified_to_common] [OPTIONS] <txt>`

<txt>: an offset file to read

Create an offset file which list offset of common string between the original and modified file. At least one size must be provided

OPTIONS:

- `-s N/--old_size=N`: size of original file (in characters)
- `-S N/--new_size=N`: size of modified file (in characters)
- `-p X/--output=X`: name of output common offset file to write
- `-h/--help`: this help

Other Usage: DumpOffsets [-M/--convert_modified_to_common] [OPTIONS] <txt>

<txt>: an offset file to read

Create a standard modified offset file from offset of common string between the original and modified file. Both size must be provided

OPTIONS:

- -s N/--old_size=N: size of original file (in characters)
- -S N/--new_size=N: size of modified file (in characters)
- -p X/--output=X: name of output common offset file to write
- -h/--help: this help

Other Usage: DumpOffsets -o <list_of_position_file_to_read.txt>

<list_of_position_file_to_read.txt> is a text file with just one number (a position) at each line.

This will convert a list of position using the offset file. The created file contain the converted position at each line, with a + at the end of line if the character at this position is on result file, a - is it was removed.

- -p <list_to_create> -T <offset_file_to_read>

Using -t instead -T will do the reverse translation

OPTIONS:

- -d/--denormalize=: Denormalize the output

This programs reproduces the white spaces removed by Normalize. It also adds the text deleted by the Preprocessing or by a graph. It preserves the text added as long as it is between the brackets (<,>).

The file fichier_dump contains the text of the file fichier version 1 and the text added in the file fichier version 2.

```
DumpOffsets [OPTIONS] -d -o <fichier_version1>
-n <fichier_version2> <fichier_offset> -p <fichier_dump>
```

13.14 Elag

Elag [OPTIONS] <tfst>

This program takes a `.tfst` text automaton <tfst> and applies to it ambiguity removal rules.

OPTIONS:

- `-l LANG/--language=LANG`: ELAG configuration file for the language of the text;
- `-r RULES/--rules=RULES`: rule file compiled in the `.rul` format;
- `-o OUT/--output=OUT`: output text automaton.

13.15 ElagComp

ElagComp [OPTIONS]

This program compiles the ELAG grammar named `GRAMMAR`, or all the grammars specified in the `RULES` file. The result is stored in the `OUT` file that will be used by the `Elag` program.

OPTIONS:

- `-r RULES/--rules=RULES`: file listing ELAG grammars;
- `-g GRAMMAR/--grammar=GRAMMAR`: single ELAG grammars;
- `-l LANG/--language=LANG`: ELAG configuration file for the language of the grammar(s);
- `-o OUT/--output=OUT`: output file. By default, the output file name is the same as `RULES`, except for the extension that is `.rul`.

13.16 Evamb

Evamb [OPTIONS] <tfst>

This program computes an average lexical ambiguity rate on the text automaton <tfst>, or just on the sentence which number is specified by `N`. The results of the computation are displayed on the standard output. The text automaton is not modified.

OPTIONS:

- `-o OUT/--output=OUT`: optional output filename;
- `-s N/--sentence=N`: sentence number.

13.17 Extract

Extract [OPTIONS] <text>

This program extracts from the given text all sentences that contain at least one occurrence from the concordance. The parameter <text> represents the complete path of the text file, without omitting the extension `.snt`.

OPTIONS:

- `-y/--yes`: extracts all sentences containing matching units (default);
- `-n/--no`: extracts all sentences that don't contain matching units;
- `-o OUT/--output=OUT`: output text file;
- `-i X/--index=X`: the `.ind` file that describes the concordance. By default, `X` is the `concord.ind` file located in the text directory.

The result file is a text file that contains all extracted sentences, one sentence per line.

13.18 Flatten

Flatten [OPTIONS] <fst2>

This program takes a `.fst2` grammar as its parameter, and tries to transform it into a finite-state transducer.

OPTIONS:

- `-f/--fst`: the grammar is "unfolded" to the maximum depth and is truncated if there are calls to sub-graphs. Truncated calls are replaced by void transitions. The result is a `.fst2` grammar that only contains a single finite-state transducer;
- `-r/--rtn`: calls to sub-graphs that remain after the transformation are left as they are. The result is therefore a finite-state transducer in the favorable case, and an optimized grammar strictly equivalent to the original grammar if not (default);
- `-d N/--depth=N`: maximum depth to which graph calls should be unfolded. The default value is 10.

13.19 Fst2Check

```
Fst2Check [OPTIONS] <fst2>
```

This program checks if a .fst2 file has no error for Locate.

OPTIONS:

- `-y/--loop_check`: enables error checking (loop detection);
- `-n/--no_loop_check`: disables error checking (default);
- `-t/--tfst_check`: checks whether the given graph can be considered as a valid sentence automaton or not;
- `-e/--no_empty_graph_warning`: no warning will be emitted when a graph matches the empty word. This option is used by `MultiFlex` in order not to scare users with meaningless error messages when they design an inflection grammar that matches the empty word.

Output options:

- `-o file/--output=file`: output file for error message;
- `-a/--append`: opens the message output file in append mode;
- `-s/--statistics`: displays statistics about fst2 file.

13.20 Fst2List

```
Fst2List [-o out][-p s/f/d][-[a/t] s/m][-m][-f s/a][-s[0s] "Str"]
        [-r[s/l] "Str"] [-l line#] [-i subname]*
        [-c SS=0xxxx]* fname
```

This program takes a .fst2 file and lists the sequences recognized by this grammar. The parameters are:

- `fname`: grammar name, including .fst2;
- `-o out`: specifies the output file, `lst.txt` by default;
- `-S`: display result on standard output. Exclusive with `-o`;
- `-[a/t] s/m`: indicates if the program must take into account (t) or not (a) the outputs of the grammars if any. `s` indicates that there is only one initial state, whereas `m` indicates that there are several ones (this mode is useful in Korean). The default value is `-a s`;

- `-l line#` : maximum number of lines to be printed in the output file;
- `-i subname` : indicates that the recursive exploration must end when the program enters in graph `subname`. This parameter can be used several times in order to specify several stop graphs;
- `-p s/f/d` : `s` displays paths graph by graph; `f` (default) displays global paths; `d` displays global paths with information on nested graph calls;
- `-c SS=0XXXX` : replaces symbol `SS` when it appears between angle brackets by the Unicode character whose hexadecimal number is `0XXXX`;
- `-s "L[,R]"` : specifies the left (`L`) and right (`R`) delimiters that will enclose items. By default, no delimiters are specified;
- `-s0 "Str"` : if the program must take outputs into account, this parameter specifies the sequence `Str` that will be inserted between input and output. By default, there is no separator;
- `-f a/s` : if the program must take outputs into account, this parameter specifies the format of the lines that will be generated: `in0 in1 out0 out1 (s)` or `in0 out0 in1 out1 (a)`. The default value is `s`;
- `-ss "stop"` : set `"str"` as the mark of stop exploitation at `"<stop>"`. The default value is `null`
- `-v` : prints information during the process (verbose mode);
- `-m` : mode special for description with alphabet
- `-rx "L, [R]"` : specifies how cycles must be displayed. `L` and `R` are delimiters. If we consider the graph shown on Figure 13.4, here are the results for `L="["` and `R="] *"`:

```
il fait [très très]*
il fait très beau
```

Figure 13.4: Graph with a cycle

13.21 Fst2Txt

Fst2Txt [OPTIONS] <fst2>

This program applies a transducer to a text in longest match mode at the preprocessing stage, when the text has not been cut into lexical units yet.

OPTIONS:

- `-t TXT/--text=TXT`: the text file to be modified, with extension `.snt`;
- `-a ALPH/--alphabet=ALPH`: the alphabet file of the language of the text;
- `-s/--start_on_space`: this parameter indicates that the search will start at any position in the text, even before a space. This parameter should only be used to carry out morphological searches;
- `-x/--dont_start_on_space`: forbids the program to match expressions that start with a space (default);
- `-c/--char_by_char`: works in character by character tokenization mode. This is useful for languages like Thai;
- `-w/--word_by_word`: works in word by word tokenization mode (default);

Output options:

- `-M/--merge`: merge transducer outputs with text inputs (default);
- `-R/--replace`: replace texts inputs with corresponding transducer outputs.

This program modifies the input text file.

13.22 Grf2Fst2

Grf2Fst2 [OPTIONS] <grf>

This program compiles a grammar into a `.fst2` file (for more details see section 6.2). The parameter <grf> denotes the complete path of the main graph of the grammar, without omitting the extension `.grf`.

OPTIONS:

- `-y/--loop_check`: enables error checking (loop detection);
- `-n/--no_loop_check`: disables error checking (default);

- `-a ALPH/--alphabet=ALPH`: specifies the alphabet file to be used for tokenizing the content of the grammar boxes into lexical units;
- `-c/--char_by_char`: tokenization will be done character by character. If neither `-c` nor `-a` option is used, lexical units will be sequences of any Unicode letters.
- `-d DIR/--pkgdir=DIR`: specifies the repository directory to use (see section 5.2.2, page 99).
- `-e/--no_empty_graph_warning`: no warning will be emitted when a graph matches the empty word. This option is used by `MultiFlex` in order not to scare users with meaningless error messages when they design an inflection grammar that matches the empty word.
- `-t/--tfst_check`: checks whether the given graph can be considered as a valid sentence automaton or not.
- `-s/--silent_grf_name`: does not print the graph names (needed for consistent log files across several systems).
- `-r XXX/--named_repositories=XXX`: declaration of named repositories. XXX is made of one or more X=Y sequences, separated by ';', where X is the name of the repository denoted by pathname Y. You can use this option several times.
- `--debug`: compile graphs in debug mode.
- `-v/check_variables`: check output validity to avoid malformed variable expressions.

The result is a file with the same name as the graph passed to the program as a parameter, but with extension `.fst2`. This file is saved in the same directory as `<grf>`.

13.23 GrfDiff

`GrfDiff <grf1> <grf2>`: .grf files to be compared

OPTIONS:

- `--output X`: saves the result, if any, in X instead of printing it on the output

Compares the given grf files and prints their difference on the standard output. Returns 0 if they are identical modulo box and transition reordering, 1 if there are differences, 2 in case of error.

Here are the diff indications that can be emitted:

- **P name**: a presentation property has changed. name=property name (SIZE, FONT, ...)
- **M a b**: box moved. a=box number in <grf1>, b=box number in <grf2>
- **C a b**: box content changed. a=box number in <grf1>, b=box number in <grf2>
- **A x**: box added. x=box number in <grf2>
- **R x**: box removed. x=box number in <grf1>
- **T a b x y**: transition added. a,b=src and dst box numbers in <grf1>. x,y=src and dst box numbers in <grf2>
- **X a b x y**: transition removed. a,b=src and dst box numbers in <grf1>. x,y=src and dst box numbers in <grf2>

Note that transition modifications related to boxes that have been added or removed are not reported.

13.24 GrfDiff3

GrfDiff3 <mine> <base> <other>

<mine>: my .grf file <other>: the other .grf file that may be conflicting <base>: the common ancestor .grf file

OPTIONS:

- **--output X**: saves the result, if any, in X instead of printing it on the output
- **--conflicts X**: saves the description of the conflicts, if any, in X
- **--only-cosmetic**: reports a conflict for any change that is not purely cosmetic

Tries to merge <mine> and <other>. In case of success, the result is printed on the standard output and 0 is returned. In case of unresolved conflicts, 1 is returned and nothing is printed. 2 is returned in case of error.

13.25 ImplodeTfst

ImplodeTfst [OPTIONS] <tfst>

This program implodes the specified text automaton by merging together lexical entries which only differ in their inflectional features.

OPTIONS:

- `-o OUT/--output=OUT`: output file. By default, the input text automaton is modified.

13.26 Locate

Locate [OPTIONS] <fst2>

This program applies a grammar to a text and constructs an index of the occurrences found.

OPTIONS:

- `-t TXT/--text=TXT`: complete path of the text file, without omitting the `.snt` extension;
- `-a ALPH/--alphabet=ALPH`: complete path of the alphabet file;
- `-m DICS/--morpho=DICS`: this optional parameter indicates which morphological-mode dictionaries are to be used, if needed by some `.fst2` dictionaries. `DICS` represents a list of `.bin` files (with full paths) separated with semi-colons;
- `-s/--start_on_space`: this parameter indicates that the search will start at any position in the text, even before a space. This parameter should only be used to carry out morphological searches;
- `-x/--dont_start_on_space`: forbids the program to match expressions that start with a space (default);
- `-c/--char_by_char`: works in character by character tokenization mode. This is useful for languages like Thai;
- `-w/--word_by_word`: works in word by word tokenization mode (default);
- `-d DIR/--sntdir=DIR`: puts produced files in `DIR` instead of the text directory. Note that `DIR` must end with a file separator (`\` or `/`);
- `-K/--korean`: tells `Locate` that it works on Korean;
- `-u X/--arabic_rules=X`: Arabic typographic rule configuration file;
- `-g X/--negation_operator=X`: specifies the negation operator to be used in `Locate` patterns. The two legal values for `X` are `minus` and `tilde` (default). Using `minus` provides backward compatibility with previous versions of `Uniflex`.

Search limit options:

- `-l/--all`: looks for all matches (default);

- `-n N/--number_of_matches=N`: stops after the first N matches.

Maximum iterations per token options:

- `-o N/--stop_token_count=N`: stops after N iterations on a token;
- `-o N,M/--stop_token_count=N,M`: emits a warning after N iterations on a token and stops after M iterations.

Matching mode options:

- `-S/--shortest_matches`;
- `-L/--longest_matches` (default);
- `-A/--all_matches`.

Output options:

- `-I/--ignore`: ignore transducer outputs (default);
- `-M/--merge`: merge transducer outputs with text inputs;
- `-R/--replace`: replace texts inputs with corresponding transducer outputs;
- `-p/--protect_dic_chars`: when `-M` or `-R` mode is used, `-p` protects some input characters with a backslash. This is useful when `Locate` is called by `Dico` in order to avoid producing bad lines like:

```
3,14,.PI.NUM
```
- `-v X=Y/--variable=X=Y`: sets an output variable named X with content Y. Note that Y must be ASCII.

Ambiguous output options:

- `-b/--ambiguous_outputs`: allows the production of several matches with same input but different outputs (default);
- `-z/--no_ambiguous_outputs`: forbids ambiguous outputs. In case of ambiguous outputs, one will be arbitrarily chosen and kept, depending on the internal state of the program.

Variable error options

These options have no effect if the output mode is set with `--ignore`; otherwise, they rule the behavior of the `Locate` program when an output is found that contains a reference to a variable that is not correctly defined.

- `-X/--exit_on_variable_error`: kills the program;
- `-Y/--ignore_variable_errors`: acts as if the variable has an empty content (default);
- `-Z/--backtrack_on_variable_errors`: stop exploring the current path of the grammar.

Variable injection:

- `-v X=Y/--variable=X=Y`: sets an output variable named `X` with content `Y`. Note that `Y` must be ASCII

This program saves the references to the found occurrences in a file called `concord.ind`. The number of occurrences, the number of units belonging to those occurrences, as well as the percentage of recognized units within the text are saved in a file called `concord.n`. These two files are stored in the directory of the text.

13.27 LocateTfst

`LocateTfst [OPTIONS] <fst2>`

Applies a grammar to a text automaton, and saves the matching sequence index in a file named `concord.ind`, just as `Locate` does.

OPTIONS:

- `-t TFST/--text=TFST`: complete path of the text automaton, without omitting the `.tfst` extension;
- `-a ALPH/--alphabet=ALPH`: complete path of the alphabet file;
- `-K/--korean`: tells `LocateTfst` that it works on Korean;
- `-g X/--negation_operator=X`: specifies the negation operator to be used in `Locate` patterns. The two legal values for `X` are `minus` and `tilde` (default). Using `minus` provides backward compatibility with previous versions of `Uniflex`.

Search limit options:

- `-l/--all`: looks for all matches (default);
- `-n N/--number_of_matches=N`: stops after the first `N` matches.

Matching mode options:

- `-S/--shortest_matches`;
- `-L/--longest_matches` (default);
- `-A/--all_matches`.

Output options:

- `-I/--ignore`: ignore transducer outputs (default);
- `-M/--merge`: merge transducer outputs with text inputs;
- `-R/--replace`: replace texts inputs with corresponding transducer outputs.

Ambiguous output options:

- `-b/--ambiguous_outputs`: allows the production of several matches with same input but different outputs (default);
- `-z/--no_ambiguous_outputs`: forbids ambiguous outputs. In case of ambiguous outputs, one will be arbitrarily chosen and kept, depending on the internal state of the program.

Variable error options

These options have no effect if the output mode is set with `--ignore`; otherwise, they rule the behavior of the `Locate` program when an output is found that contains a reference to a variable that is not correctly defined.

- `-X/--exit_on_variable_error`: kills the program;
- `-Y/--ignore_variable_errors`: acts as if the variable has an empty content (default);
- `-Z/--backtrack_on_variable_errors`: stop exploring the current path of the grammar.

Variable injection

- `-v X=Y/--variable=X=Y`: sets an output variable named X with content Y. Note that Y must be ASCII.

Tagging option

- `--tagging`: indicates that the concordance must be a tagging one, containing additional information on the start and end states of each match.

This program saves the references to the found occurrences in a file called `concord.ind`. The number of occurrences and the number of produced outputs are saved in a file called `concord_tfst.n`. These two files are stored in the directory of the text.

13.28 MultiFlex

MultiFlex [OPTIONS] <delaf>

This program carries out the automatic inflection of a DELA dictionary containing simple (see section 3.1.2) or compound word lemmas (see chapter 11).

OPTIONS:

- `-o DELAF/--output=DELAF`: output DELAF file;
- `-a ALPH/--alphabet=ALPH`: alphabet file;
- `-d DIR/--directory=DIR`: the directory containing Morphology and Equivalences files and inflection graphs for single and compound words;
- `-K/--korean`: tells MultiFlex that it works on Korean;
- `-s/--only-simple-words`: the program will consider compound words as errors;
- `-c/--only-compound-words`: the program will consider simple words as errors;
- `-p DIR/--pkgdir=DIR`: specifies the graph repository.
- `-rXXX/--named_repositories=XXX`: declaration of named repositories. XXX is made of one or more X=Y sequences, separated by ; where X is the name of the repository denoted by the pathname Y. You can use this option several times.

Note that `.fst2` inflection transducers will automatically be built from corresponding `.grf` files if absent or older than `.grf` files.

13.29 Normalize

Normalize [OPTIONS] <text>

This program carries out a normalization of text separators. The separators are space, tab, and newline. Every sequence of separators that contains at least one newline is replaced by a unique newline. All other sequences of separators are replaced by a single space.

This program also checks the syntax of lexical tags found in the text. All sequences in curly brackets should be either the sentence delimiter {S}, the stop marker {STOP}, or valid entries in the DELAF format ({aujourd'hui, .ADV}).

Parameter `<text>` represents the complete path of the text file. The program creates a modified version of the text that is saved in a file with extension `.snt`.

OPTIONS:

- `-n/--no_carriage_return`: every separator sequence will be turned into a single space;
- `--input_offsets=XXX`: base offset file to be used.
- `--output_offsets=XXX`: offset file to be produced.
- `-r XXX/--replacement_rules=XXX`: specifies the normalization rule file to be used. See section 14.13.6 for details about the format of this file. By default, the program only replaces `{` and `}` by `[` and `]`.
- `--no_separator_normalization`: only applies replacement rules specified with `-r`

WARNING: if you specify a normalization rule file, its rules will be applied prior to anything else. So, you have to be very careful if you manipulate separators in such rules.

13.30 PolyLex

PolyLex [OPTIONS] `<list>`

This program takes a file containing unknown words `<list>` and tries to analyse each of the words as a compound obtained by concatenating simple words. The words that have at least one analysis are removed from the file of unknown words and the dictionary lines that correspond to the analysis are appended to file `OUT`.

OPTIONS:

- `-a ALPH/--alphabet=ALPH`: the alphabet file to use;
- `-d BIN/--dictionary=BIN`: .bin dictionary to use;
- `-o OUT/--output=OUT`: designates the file in which the produced dictionary lines are to be printed; if that file already exists, the produced lines are appended at the end of the file;
- `-i INFO/--info=INFO`: designates a text file in which the information about the analysis has been produced.

Language options:

- -D/--dutch
- -G/--german
- -N/--norwegian
- -R/--russian

NOTE: for Dutch or Norwegian words, the program tries to read a text file containing a list of forbidden words. This file is supposed to be named `ForbiddenWords.txt` (see section 14.13.7) and stored in the same directory than `BIN`.

13.31 RebuildTfst

RebuildTfst <tfst>

This program reconstructs text automaton <tfst> taking into account the manual modifications. If the program finds a file `sentenceN.grf` in the same directory as <tfst>, it replaces the automaton of sentence N with the one represented by `sentenceN.grf`. The input text automaton is modified.

13.32 Reconstrucao

Reconstrucao [OPTIONS] <index>

This program generates a normalization grammar designed to be applied before the construction of an automaton for a Portuguese text. The <index> file represents a concordance which has to be produced by applying in MERGE mode to the considered text a grammar that extracts all forms to be normalized. This grammar is called `V-Pro-Suf`, and is stored in the `/Portuguese/Graphs/Normalization` directory.

OPTIONS:

- -a ALPH/--alphabet=ALPH: the alphabet file to use;
- -r ROOT/--root=ROOT: the inverse `.bin` dictionary to use to find forms in the future and conditional given their canonical forms. It has to be obtained by compressing the dictionary of verbs in the future and conditional with the parameter `--flip` (see section 13.8);
- -d BIN/--dictionary=BIN: the `.bin` dictionary to use;
- -p PRO/--pronoun_rules=PRO: the `.fst2` grammar describing pronoun rewriting rules;

- `-n PRO/--nasal_pronoun_rules=PRO`: the `.fst2` grammar describing nasal pronoun rewriting rules;
- `-o OUT/--output=OUT`: the name of the `.grf` graph to be generated.

13.33 Reg2Grf

Reg2Grf <txt>

This program constructs a `.grf` file corresponding to the regular expression written in file <txt>. The parameter <txt> represents the complete path to the file containing the regular expression. This file needs to be a Unicode text file. The program takes into account all characters up to the first newline. The result file is called `regexp.grf` and is saved in the same directory as <txt>.

13.34 Seq2Grf

Seq2Grf [OPTIONS] <snt>

This program constructs a `.grf` file corresponding to the sequences contained in file <snt>.

OPTIONS:

- `-a ALPH/--alphabet=ALPH`: the alphabet file to use;
- `-o XXX/--output=XXX`: output GRF file;
- `-s/--only-stop`: only consider STOP-separated sequences;
- `-b/--beautify`: apply the grf beautifying algorithm;
- `-n/--no_beautify`: do not apply the grf beautifying algorithm (default);
- `--case-sensitive`: all letter tokens are protected with double-quotes (default);
- `--case-insensitive`: letter tokens are not protected with double-quotes;
- `-w x`: number of wildcards;
- `-i x`: number of insertions;
- `-r x`: number of replations;
- `-d x`: number of deletions;

Constructs the sequences automaton : one single automaton that recognizes all the sequences from the SNT. The sequences must be delimited with the special tag {STOP}. The produced .grf file is stored in the user's Graphs directory. The other files, named `text.tfst`, `text.tind` are stored in the text directory.

13.35 SortTxt

SortTxt [OPTIONS] <txt>

This program carries out a lexicographical sorting of the lines of file <txt>. <txt> represents the complete path of the file to be sorted.

OPTIONS:

- `-n/--no_duplicates`: remove duplicate lines (default);
- `-d/--duplicates`: remove duplicate lines;
- `-r/--reverse`: sort in descending order;
- `-o XXX/--sort_order=XXX`: sorts using the alphabet of the order defined by file XXX. If this parameter is missing, the sorting is done according to the order of Unicode characters;
- `-l XXX/--line_info=XXX`: backup the number of lines of the result file in file XXX;
- `-t/--thai`: option for sorting Thai text.
- `-f/--factorize_inflectional_codes`: makes two entries XXX,YYY.ZZZ:A and XXX,YYY.ZZZ:B become a single entry XXX,YYY.ZZZ:A:B

The input text file is modified. By default, the sorting is performed in the order of Unicode characters, removing duplicate lines.

13.36 Stats

Stats [OPTIONS] <ind>

This program computes some statistics from the <ind> concordance index file.

OPTIONS:

- `-m MODE/--mode=MODE`: specifies the output to be produced:
 - 0 = matches with left and right contexts + number of occurrences;

- 1 = collocates + number of occurrences;
- 2 = collocates + number of occurrences + z-score.
- -a ALPH/--alphabet=ALPH: alphabet file to use;
- -o OUT/--output=OUT: output file;
- -l N/--left=N: length of left contexts in tokens;
- -r N/--right=N: length of right contexts in tokens;
- -c N/--case=N: case policy: 0 = case insensitive, 1 = case sensitive (default).

13.37 Table2Grf

Table2Grf [OPTIONS] <table>

This program automatically generates graphs from a lexicon-grammar <table> and a template graph.

OPTIONS:

- -r GRF/--reference_graph=GRF: name of the template graph;
- -o OUT/--output=OUT: name of the result main graph;
- -s XXX/--subgraph_pattern=XXX: if this optional parameter is specified, all the produced subgraphs will be named according to this pattern. In order to have unambiguous names, we recommend to include @% in the parameter (remind that @% will be replaced by the line number of the entry in the table). For instance, if you set the pattern parameter to 'subgraph-@%.grf', subgraph names will be such as 'subgraph-0013.grf'. By default, subgraph names look like 'result_0013.grf', where 'result.grf' designates the result main graph.

13.38 Tagger

Tagger [OPTIONS] <tfst>

The input of this program is the text automaton in the specified .tfst. The program applies the Viterbi-Path algorithm to it and produces a linear automaton. The automaton is pruned in a probabilistic way based on a second-order hidden Markov model. If the specified tagger data file contains tuples of "cat" tags, the tagger prunes transitions on the basis of grammatical, syntactic and semantic codes (for example, that.DET+Ddem versus that.PRO+Pdem). Else if it contains tuples of "morph"

tags, so the tagger prunes transitions on grammatical, semantic, syntactic and inflectional codes (the `.DET+Ddef:s` versus the `.DET+Ddef:p`). In that case, the automaton needs to be exploded before applying the tagging process and a tagset file must be specified by the `-t` option below.

OPTIONS:

- `-a ALPH/--alphabet=ALPH`: alphabet file.
- `-o OUT/--output=OUT`: output text automaton.
- `-t TAGSET/--tagset=TAGSET`: name of the tagset description file.
- `-d DATA/--data=DATA`: a `.bin` tagger data file that contains occurrence counts for unigrams, bigrams and trigrams in order to compute probabilities. This file is obtained with the `TrainingTagger` program (see section [14.10.2](#)).

13.39 TagsetNormTfst

```
TagsetNormTfst [OPTIONS] <tfst>
```

This program normalizes the specified `.tfst` text automaton according to a tagset description file, discarding undeclared dictionary codes and incoherent lexical entries. Inflectional features are unfactorized so that `{rouge, .A:fs:ms}` will be divided into the 2 tags `{rouge, .A:fs}` and `{rouge, .A:ms}`.

OPTIONS:

- `-o OUT/--output=OUT`: output text automaton. By default, the input text automaton is modified;
- `-t TAGSET/--tagset=TAGSET`: name of the tagset description file.

13.40 TEI2Txt

```
TEI2Txt [OPTIONS] <xml>
```

Produces a raw text file from the given `<xml>` TEI file.

OPTIONS:

- `-o TXT/--output=TXT`: name of the output text file. By default, the output file has the same name than the input one, replacing `.xml` by `.txt`.

13.41 Tfst2Grf

Tfst2Grf [OPTIONS] <tfst>

This program extracts a sentence automaton in `.grf` format from the given text automaton.

OPTIONS:

- `-s N/--sentence=N`: the number of the sentence to be extracted;
- `-o XXX/--output=XXX`: pattern used to name output files `XXX.grf`, `XXX.txt` and `XXX.tok` (default=`cursentence`);
- `-f FONT/--font=FONT`: sets the font to be used in the output `.grf` (default=`Times new Roman`);
- `-z N/--fontsize=N`: sets the font size (default=10).

The program produces the following files and saves them in the directory of the text:

- `cursentence.grf`: graph representing the automaton of the sentence;
- `cursentence.txt`: text file containing the sentence;
- `cursentence.tok`: text file containing the numbers of the tokens that compose the sentence.

13.42 Tfst2Unambig

Tfst2Unambig [OPTIONS] <tfst>

This programs takes a `.tfst` text automaton and produces an equivalent text file if the automaton is linear (i.e. with no ambiguity). See section 7.6, page 190.

OPTIONS:

- `-o TXT/--out=TXT`: the output text file.

13.43 Tokenize

Tokenize [OPTIONS] <txt>

This program tokenizes a tet text into lexical units. <txt> the complete path of the text file, without omitting the `.snt` extension.

OPTIONS:

- `-a ALPH/--alphabet=ALPH`: alphabet file;
- `-c/--char_by_char`: indicates whether the program is applied character by character, with the exceptions of the sentence delimiter `{S}`, the stop marker `{STOP}` and lexical tags like `{today, .ADV}` which are considered to be single units;
- `-w/--word_by_word`: with this option, the program considers a unit to be either a sequence of letters (the letters are defined by file `alphabet`), or a character which is not a letter, or the sentence separator `{S}`, or a lexical label like `{aujourd' hui, .ADV}`. This is the default mode.
- `-t TOKENS/--tokens=TOKENS`: specifies a `tokens.txt` file to load and modify, instead of creating a new one from scratch.

Offsets options:

- `input_offsets`: base offset file to be used;
- `output_offsets`: offset file to be produced;

The program codes each unit as a whole. The list of units is saved in a text file called `tokens.txt`. The sequence of codes representing the units now allows the coding of the text. This sequence is saved in a binary file named `text.cod`. The program also produces the following four files:

- `tok_by_freq.txt`: text file containing the units sorted by frequency;
- `tok_by_alph.txt`: text file containing the units sorted alphabetically;
- `stats.n`: text file containing information on the number of sentence separators, the number of units, the number of simple words and the number of numbers;
- `enter.pos`: binary file containing the list of newline positions in the text. The coded representation of the text does not contain newlines, but spaces. Since a newline counts as two characters and a space as a single one, it is necessary to know where newlines occur in the text when the positions of occurrences located by the `Locate` program are to be synchronized with the text file. File `enter.pos` is used for this by the `Concord` program. Thanks to this, when clicking on an occurrence in a concordance, it is correctly selected in the text. File `enter.pos` is a binary file containing the list of the positions of newlines in the text.

All produced files are saved in the text directory.

13.44 TrainingTagger

TrainingTagger [OPTIONS] <txt>

This program automatically generates two tagger data files from a tagged corpus text file. They are used by the `Tagger` program in order to compute probabilities and linearize the text automaton. The tagged corpus file must follow the format described in section 14.10.1. Those files contain tuples (unigrams, bigrams and trigrams), formed by tags and words. In the first data file, tags are "cat" tags (i.e. grammatical, syntactic and semantic codes). In the second data file, tags are "morph" tags (i.e. grammatical, syntactic, semantic and inflectional codes).

OPTIONS:

- `-a/--all`: indicates whether the program should produce all data files (default);
- `-c/--cat`: indicates whether the program should produce only data file with "cat" tags;
- `-m/--morph`: indicates whether the program should produce only data file with "morph" tags;
- `-n/--no_binaries`: indicates whether the program should not compress data files into `.bin` files, in this case only `.dic` data files are generated;
- `-b/--binaries`: indicates whether the program should compress data files into `.bin` files (default);
- `-o XXX/--output=XXX`: pattern used to name output tagger data files `XXX_data_cat.bin` and `XXX_data_morph.bin` (default=filename of text corpus without extension);
- `-s/--semitic`: indicates that the semitic compression algorithm should be used.

13.45 Txt2Tfst

Txt2Tfst [OPTIONS] <txt>

This program constructs an automaton of a text. <txt> represents the complete path of a text file without omitting the `.snt` extension.

OPTIONS:

- `-a ALPH/--alphabet=ALPH`: alphabet file;

- `-c/--clean`: indicates whether the rule of conservation of the best paths (see section 7.2.4) should be applied;
- `-n XXX/--normalization_grammar=XXX`: name of a normalization grammar that is to be applied to the text automaton;
- `-t TAGSET/--tagset=TAGSET`: Elag tagset file to use to normalize dictionary entries;
- `-K/--korean`: tells `Txt2Tfst` that it works on Korean.

If the text is separated into sentences, the program constructs an automaton for each sentence. If this is not the case, the program arbitrarily cuts the text into sequences of 2000 tokens and produces an automaton for each of these sequences.

The result is a file called `text.tfst` which is saved in the directory of the text. Another file named `text.tind` is also produced.

NOTE: The program will also try to use the `tags.ind` file, if any (see section 14.7.4).

13.46 Uncompress

```
Uncompress [OPTIONS] <bin>
```

This program uncompresses a `.bin` dictionary into a text file `.dic` one.

OPTIONS:

- `-o OUT/--output=OUT`: optional output file name (default: `file.bin > file.dic`).

13.47 Untokenize

```
Untokenize [OPTIONS] <txt>
```

Untokenizes and rebuild the original text. The token list is stored into `tokens.txt` and the coded text is stored into `text.cod`. The file `enter.pos` contains the position in tokens of all the carriage return sequences. These files are located in the `XXX_snt` directory where `XXX` is `<txt>` without its extension.

OPTIONS:

- `-d X/--sntdir=X`: uses directory `X` instead of the text directory; note that `X` must be (back)slash terminated

- `-n N/--number_token=N`: adds tokens number each N token;
- `-r N/--range=N`: emits only token from number N to end;
- `-r N,M/--range=N,M`: emits only token from number N to M.

13.48 UnitexTool

UnitexTool <utilities>

This program is a super-program that allows you to invoke all Unitex external programs. With it, you can chain commands so that they will be invoked within a same system process, in order to speed up processing. This can be done by invoking commands nested in round brackets as this:

```
UnitexTool { SelectOutput [OPTIONS] }
            { cmd #1+args }
            { cmd #2+args }
            etc.
```

For instance, if you want to join a locate operation and the construction of the concordance, you can use the following command:

```
UnitexTool { Locate "-tD:\My Unitex\English\Corpus\ivanhoe.snt"
"D:\My Unitex\English\regexp.fst2"
"-aD:\My Unitex\English\Alphabet.txt" -L -I -n200
"--morpho=D:\Unitex2.0\English\Dela\del-en-public.bin" -b -Y }
{ Concord "D:\My Unitex\English\Corpus\ivanhoe_snt\concord.ind"
"-fCourier new" -s12 -l40 -r55 --CL --html
"-aD:\My Unitex\English\Alphabet_sort.txt" }
```

OPTIONS:

- `-o [on/off]/--output=[on/off]`: enable (on) or disable (off) standard output
- `-e [on/off]/--error=[on/off]`: enable (on) or disable (off) error output

By example:

```
UnitexTool { SelectOutput -o off -e off } { Normalize
Unitex\English\Corpus\ivanhoe.txt }
```

13.49 UnitexToolLogger

UnitexToolLogger <utilities>

This program is a superset of UnitexTool. It can rerun a .ulp logfile. It can also record a running session of an UnitexTool and create a .ulp logfile. If UnitexToolLogger is used like UnitexTool (with just parameters with command lines for Unitex external programs), and if a file named `unitex_logging_parameters_count.txt` (in the current directory) contains a path, a .ulp logfile for the running session will be created. The .ulp file is a compressed zipfile (compatible with unzip), which can be useful for debugging.

```
UnitexToolLogger RunLog [OPTIONS] <ulp>
```

OPTIONS after RunLog:

- `-m/--quiet`: do not emit message when running;
- `-v/--verbose`: emit message when running;
- `-d DIR/--rundir=DIR`: path where log is executed;
- `-r newfile.ulp/--result=newfile.ulp`: name of result ulp created;
- `-c/--clean`: remove work file after execution;
- `-k/--keep`: keep work file after execution;
- `-s file.txt/--summary=file.txt`: summary file with log compare result to be created;
- `-e file.txt/--summary-error=file.txt`: summary file with error compare result to be created;
- `-b/--no-benchmark`: do not store time execution in result log;
- `-n/--cleanlog`: remove result ulp after execution;
- `-l/--keeplog`: keep result ulp after execution;
- `-o NameTool/--tool=NameTool`: run only log for NameTool;
- `-i N/--increment=N`: increment filename <ulp> by 0 to N;
- `-t N/--thread=N`: create N thread;
- `-a N/--random=N`: select N time a random log in the list (in each thread);
- `-f N/--break-after=N`: user cancel after N run (with one thread only);

- `-u PATH/--unfound-location=PATH`: take dictionary and FST2 from PATH if not found on the logfile;

Another usage of `UnitexToolLogger` is using the `MzRepairUlp` option to repair a corrupted ulp file (often, a crashing log):

```
UnitexToolLogger MzRepairUlp [OPTIONS] <ulpfile>
```

OPTIONS after MzRepairUlp:

- `-t X/--temp=X`: uses X as filename for temporary file (<ulpfile>.build by default);
- `-o X/--output=X`: uses X as filename for fixed .ulp file (<ulpfile>.repair by default);
- `-m/--quiet`: do not emit message when running;
- `-v/--verbose`: emit message when running;

Another usage of `UnitexToolLogger` is using the `CreateLog` option (with round bracket) to create logfile of running Unitex program, like:

```
UnitexToolLogger { CreateLog [OPTIONS] } cmd args
```

```
UnitexToolLogger { CreateLog [OPTIONS] } { cmd #1+args } { cmd #2+args }
By example,
```

```
UnitexToolLogger { CreateLog --log_file=my_run_normalize.ulp }
                  Normalize "C:\My Unitex\French\Corpus\80jours.txt"
```

```
UnitexToolLogger { CreateLog --directory=c:\logs }
                  { Compress c:\dela\mydela.dic }
                  { CheckDic --delaf c:\dela\mydela.inf }
```

OPTIONS after CreateLog:

- `-g/--no_create_log`: do not create any log file. Incompatible with all others options;
- `-p XXX/--param_file=XXX`: load a parameters file like `unitex_logging_parameters.txt`. Incompatible with all others options;
- `-d XXX/--directory=XXX`: location directory where log file to create;
- `-l XXX/--log_file=XXX`: filename of log file to create;

- `-i/--store_input_file`: store input file in log (default);
- `-n/--no_store_input_file`: don't store input file in log (prevent rerun the logfile);
- `-o/--store_output_file`: store output file in log;
- `-u/--no_store_output_file`: don't store output file in log (default);
- `-s/--store_list_input_file`: store list of input file in log (default);
- `-t/--no_store_list_input_file`: don't store list of input file in log;
- `-r/--store_list_output_file`: store list of output file in log (default);
- `-f/--no_store_list_output_file`: don't store list of output file in log.

```
UnitexToolLogger { SelectOutput [OPTIONS] }
                  { cmd #1+args }
                  { cmd #2+args }
                  etc.
```

OPTIONS after SelectOutput:

- `-o [on/off]/--output=[on/off]`: enable (on) or disable (off) standard output
- `-e [on/off]/--error=[on/off]`: enable (on) or disable (off) error output

By example:

```
UnitexToolLogger { SelectOutput -o off -e off } { Normalize
Unitex\English\Corpus\ivanhoe.txt }
```

13.50 Unxmlize

This program removes all xml tags from the given .xml or .html file to produce a text file that can be processed by Unitex. `Unxmlize [OPTIONS] <file>`

OPTIONS:

- `-o TXT/--output=TXT`: output file. By default, `foo.xml => foo.txt`
- `--output_offset=XXX`: specifies the offset file to be produced

- `--PRLG=XXX`: extracts to file `XXX` special information used in the PRLG project on ancient Greek (requires `--output_offsets`)
- `-t/--html`: consider the file as html file (disregard extension)
- `-x/--xml`: consider the file as xml file (disregard extension)
- `-l/--tolerate`: try tolerate some markup language malformation
- `--comments=IGNORE`: every comment is removed (default)
- `--comments=SPACE`: every comment is replaced by a single space
- `--scripts=IGNORE`: every script block is removed
- `--scripts=SPACE`: every comment is replaced by a single space (default for `.html`)

Note: by default, script tags are handled as normal tags (default for `.xml`).

- `--normal_tags=IGNORE`: every other tag is removed (default for `.xml`)
- `--normal_tags=SPACE`: every other tag is replaced by a single space (default for `.html`)

13.51 XMLizer

`XMLizer [OPTIONS] <txt>`

This program takes the raw text file `<txt>` and produces a corresponding basic TEI or XML file. The difference between TEI and XML is that TEI files will contain a TEI header.

OPTIONS:

- `-x/--xml`: produces a XML file;
- `-t/--tei`: produces a TEI file (default);
- `-n XXX/--normalization=XXX`: specify the normalization rule file to be used (see section [14.13.6](#));
- `-o OUT/--output=OUT`: optional output file name (default: `file.txt > file.xml`);
- `-a ALPH/--alphabet=ALPH`: alphabet file;
- `-s SEG/--segmentation_grammar=SEG`: sentence delimitation grammar to be used. This grammar should be like the `Sentence.grf` one used during the preprocessing of a corpus, but it can include the special tag `{P}` to indicate paragraph bounds.

Chapter 14

File formats

This chapter presents the formats of files read or generated by Unitex. The formats of the DELAS and DELAF dictionaries have already been presented in sections [3.1.1](#) and [3.1.2](#).

NOTE: In this chapter the symbol ¶ represents the newline symbol. Unless otherwise indicated, all text files described in this chapter are encoded in Unicode Little-Endian.

14.1 Unicode encoding

By default, text files processed by Unitex have to be encoded in Unicode Little-Endian. Unitex accepts also Unicode Big-Endian or UTF-8 files. This encoding allows the representation of 65536 characters by coding each of them in 2 bytes. In Little-Endian, the bytes are in lo-byte hi-byte order. If this order is reversed, we speak of Big-Endian. A text file encoded in Unicode Little-Endian, Big-Endian or UTF-8 starts with the special character (Unicode Byte Order Mark - BOM) with the hexadecimal value FF FE (Little-Endian), FE FF (Big-Endian) or EF BB BF (UTF-8). Because UTF-8 has no byte order, adding a UTF-8 BOM is optional; for UTF-16 it is required. The newline symbols have to be encoded by the two characters 0D 00 and 0A 00 (Little-Endian), 00 0D and 00 0A (Big-Endian), or 0D and 0A (UTF-8).

Consider the following text:

```
Unitex¶  
β-version¶
```

Here is its representation in Unicode Little-Endian:

BOM header	U	n	i	t	e	x	¶	β
FF FE	55 00	6E 00	69 00	74 00	65 00	78 00	0D 00 0A 00	B2 03
-	v	e	r	s	i	o	n	¶
2D 00	76 00	65 00	72 00	73 00	69 00	6F 00	6E 00	0D 00 0A 00

Table 14.1: Hexadecimal representation of a Unicode Little-Endian text

Here is its representation in Unicode Big-Endian:

BOM header	U	n	i	t	e	x	¶	β
FE FF	00 55	00 6E	00 69	00 74	00 65	00 78	00 0D 00 0A	03 B2
-	v	e	r	s	i	o	n	¶
00 2D	00 76	00 65	00 72	00 73	00 69	00 6F	00 6E	00 0D 00 0A

Table 14.2: Hexadecimal representation of a Unicode Big-Endian text

Here is its representation in Unicode UTF-8:

BOM header	U	n	i	t	e	x	¶	β
EF BB BF	55	6E	69	74	65	78	0D 0A	CE B2
-	v	e	r	s	i	o	n	¶
2D	76	65	72	73	69	6F	6E	0D 0A

Table 14.3: Hexadecimal representation of a Unicode UTF-8 text

On Unicode Little-Endian, the hi-bytes and lo-bytes have been reversed, which explains why the start character is encoded as FF FE in stead of FE FF, and 00 0D and 00 0A are 0D 00 and 0A 00 respectively.

14.2 Alphabet files

There are two kinds of alphabet files: a file which defines the characters of a language, and a file that indicates the sorting preferences. The first is designed under the name *alphabet*, the second under the name *sorted alphabet*.

14.2.1 Alphabet

The alphabet file is a text file that describes all characters of a language, as well as the correspondances between capitalized and non-capitalized letters. This file is called

Alphabet.txt and is found in the root of the directory of a language. Its presence is obligatory for Unitex to function.

Example: the English alphabet file has to be in the directory `.../English/`

Each line of the alphabet file must have one of the following three forms, followed by a newline symbol:

- **#가힐** : a hash symbol followed by two characters X and Y which indicate that all characters between X and Y are letters. All these characters are considered to be in non-capitalized and capitalized form at the same time. This method is used to define the alphabets of Asian languages like Korean, Chinese or Japanese where there is no distinction between upper- and lower-case, and where the number of characters makes a complete enumeration tedious;
- **Aa** : two characters X and Y indicate that X and Y are letters and that X is a capitalized equivalent of the non-capitalized Y form.
- **Ⓜ**: a unique character X defines X as a letter in capitalized and non-capitalized form. This form is used to define a single Asian character.

For certain languages like French, it is possible that a lower-case letter corresponds to multiple upper-case letters. For example, e , in practice, can have the upper-case form E or E . To express this, it suffices to use multiple lines. The reverse is equally true: a capitalized letter can correspond to multiple lower-case letters. Thus, E can be the capitalization of e , $é$, $è$, $ë$ or $ê$. Here is an excerpt of the French alphabet file which defines different properties of letter e :

```
Ee¶
Eé¶
Éé¶
Eè¶
Èè¶
Eë¶
Ëë¶
Eê¶
Êê¶
```

14.2.2 Sorted alphabet

The sorted alphabet file defines the sorting priorities of the letters of a language. It is used by the `SortTxt` program. Each line of that file defines a group of letters. If a group of letters A is defined before a group of letters B , every letter of group A is inferior to every letter in group B .

The letters of a group are only distinguished if necessary. For example if the group of letters `eéèëê` has been defined, the word `ébahi` should be considered 'smaller' than `estuaire`, and also 'smaller' than `été`. Since the letters that follow `e` and `é` determine the order of the words, it is not necessary to compare letters `e` and `é` since they are of the same group. On the other hand, if the words `chantés` and `chantes` are to be sorted, `chantes` should be considered as 'smaller'. It is therefore necessary to compare the letters `e` and `é` to distinguish these words. Since the letter `e` appears first in the group `eéèëê`, it is considered to be 'smaller' than `chantés`. The word `chantes` should therefore be considered to be 'smaller' than the word `chantés`.

The sorted alphabet file allows the definition of equivalent characters. It is therefore possible to ignore the different accents as well as capitalization. For example, if the letters `b`, `c`, and `d` are to be ordered without considering capitalization and the cedilla, it is possible to write the following lines:

```
Bb¶
Ccçç¶
Dd¶
```

This file is optional. If no sorted alphabet file is specified, the `SortTxt` program sorts in the order of the Unicode encoding.

14.3 Graphs

This section presents the two graph formats: the graphic format `.grf` and the compiled format `.fst2`.

14.3.1 Format `.grf`

A `.grf` file is a text file that contains presentation information in addition to information representing the contents of the boxes and the transitions of the graph. A `.grf` file begins with the following lines:

```
#Unigraph¶
SIZE 1313 950¶
FONT Times New Roman: 12¶
OFONT Times New Roman:B 12¶
BCOLOR 16777215¶
FCOLOR 0¶
ACOLOR 12632256¶
SCOLOR 16711680¶
CCOLOR 255¶
DBOXES y¶
DFRAME y¶
```

```

DDATE y
DFILE y
DDIR y
DRIG n
DRST n
FITS 100
PORIENT L
#

```

The first line `#Unigraph` is a comment line. The following lines define the parameter values of the graph presentation:

- `SIZE x y` : defines the width x and the height y of a graph in pixels;
- `FONT name:xyz` : defines the font used for displaying the contents of the boxes. $name$ represents the name of the mode. x indicates if the text should be in bold face or not. If x is `B`, it indicates that it should be bold. For non-bold face, x should be a space. In the same way, y has value `I` if the text should be italic, a space if not. z represents the size of the text;
- `OFONT name:xyz` : defines the mode used for displaying transducer outputs. Parameters $name$, x , y , and z are defined in the same way as `FONT`;
- `BCOLOR x` : defines the background color of the graph. ' x ' represents the color in RGB format;
- `FCOLOR x` : defines the foreground color of the graph. ' x ' represents the color in RGB format;
- `ACOLOR x` : defines the color inside the boxes that correspond to the calls of sub-graphs. x represents the color in RGB format;
- `SCOLOR x` : defines the color used for writing in comment boxes (boxes that are not linked up with any others). x represents the color in RGB format;
- `CCOLOR x` : defines the color used for designing selected boxes. x represents the color in RGB format;
- `DBOXES x` : this line is ignored by Unitex. It is conserved to ensure compatibility with Intex graphs;
- `DFRAME x` : there will be a frame around the graph if x is `y`, not if it is `n`;
- `DDATE x` : puts the date at the bottom of the graph if x is `y`, not if it is `n`;
- `DFILE x` : puts the name of the file at the bottom of the graph depending on whether x is `y` or `n`;

- `DDIR x` : prints the complete path of the graph whether `x` is `y` or `n`. This option has no effect if the `DFILE` option is set to `n`;
- `DRIG x` : displays the graph from right to left or left to right depending on whether `x` is `y` or `n`;
- `DRST x` : this line is ignored by Unitex. It is conserved to ensure compatibility with Intex graphs;
- `FITS x` : this line is ignored by Unitex. It is conserved to ensure compatibility with Intex graphs;
- `PORIENT x` : this line is ignored by Unitex. It is conserved to ensure compatibility with Intex graphs;
- `#` : this line is ignored by Unitex. It serves to indicate the end of the header information.

The lines after the header give the contents and the position of the boxes in the graph. The following example corresponds to a graph recognizing a number:

```
3¶
"<E>" 84 248 1 2 ¶
"" 272 248 0 ¶
s"1+2+3+4+5+6+7+8+9+0" 172 248 1 1 ¶
```

The first line after the header indicates the number of boxes in the graph, immediately followed by a newline. This number can not be lower than 2, since a graph always has an initial and a final state.

The following lines define the boxes of the graph. The boxes are numbered starting at 0. By convention, state 0 is the initial state and state 1 is the final state. The contents of the final state is always empty.

Each box in the graph is defined by a line that has the following format:

```
contents X Y N transitions ¶
```

contents is a sequence of characters enclosed in quotation marks that represents the contents of the box. This sequence can sometimes be preceded by an `s` if the graph is imported from Intex; this character is then ignored by Unitex. The contents of the sequence is the text that has been entered in the editing line of the graph editor. Table 14.4 shows the encoding of two special sequences that are not encoded in the same way as they are entered into the `.grf` files:

Sequence in the graph editor	Sequence in the .grf file
"	\"
\"	\\\"

Table 14.4: Encoding of special sequences

NOTE: The characters between $<$ and $>$ or between $\{$ and $\}$ are not interpreted. Thus the $+$ character in sequence `"le <A+Conc>"` is not interpreted as a line separator, since the pattern `<A+Conc>` is interpreted with priority.

X and Y represent the coordinates of the box in pixels. Figure 14.1 shows how these coordinates are interpreted by Unitex.

Figure 14.1: Interpretation of the coordinates of boxes

N represents the number of outgoing transitions of the box. This number is always 0 for the final state.

The transitions are defined by the number of their target box.

Every line of the box definition ends with a newline.

14.3.2 Format .fst2

An `.fst2` file is a text file that describes a set of graphs. Here is an example of an `.fst2` file:

```
0000000002¶
```

```

-1 NP
: 1 1
: 2 2 -2 2
: 3 3
t
f
-2 Adj
: 6 1 5 1 4 1
t
f
%<E>
%the/DET
%<A>/ADJ
%<N>
%nice
@pretty
%small
f

```

The first line represents the number of graphs that are encoded in the file. The beginning of each graph is identified by a line that indicates the number and the name of the graph (-1 NP and -2 Adj in the file above).

The following lines describe the states of the graph. If the state is final, the line starts with the `t` character and with the `:` character if not. For each state, the list of transitions is a possibly empty sequence of pairs of integers:

- the first integer indicates the number of the label or sub-graph that corresponds to the transition. Labels are numbered starting at 0. Sub-graphs are represented by negative integers, which explains why the numbers preceding the names of the graphs are negative;
- the second integer represents the number of the result state after the transition. In each graph, the states are numbered starting at 0. By convention state 0 is the initial state.

Each state definition line terminates with a space. The end of each graph is marked by a line containing an `f` followed by a space and a newline.

Labels are defined after the last graph. If the line begins with the `@` character, the contents of the label is to be searched without allowing case variations. This information is not used if the label is not a word. If the line starts with a `%`, capitalization variants are authorized. If a label carries a transducer output sequence, the input and output sequences are separated by the `/` character (example: `the/DET`). By

convention, the first label is always the empty word (`<E>`), even if that label is never used for any transition.

The end of the file is indicated by a line containing the `f` character followed by a newline.

14.4 Texts

This section presents the different files used to represent texts.

14.4.1 .txt files

`.txt` files are text files encoded in Unicode Little-Endian. These files should not contain any opening or closing braces, except for those used to mark a sentence delimiter (`{S}`) or a valid lexical tag (`{aujourd'hui, .ADV}`). The newline needs to be encoded with the two special characters with hexadecimal values `000D` and `000A`.

14.4.2 .snt files

`.snt` files are `.txt` files that have been processed by Unitex. These files should not contain any tabs. They should also not contain multiple consecutive spaces or newlines. The only allowed braces in `.snt` files are those of the sentence delimiter `{S}` and those of lexical labels (`{aujourd'hui, .ADV}`).

14.4.3 File `text.cod`

The `text.cod` file is a binary file containing a sequence of integers that represent the text. Each integer `i` reflects the token with index `i` in the `tokens.txt` file. These integers are encoded in four bytes.

NOTE: Tokens are numbered starting at 0.

14.4.4 The `tokens.txt` file

The `tokens.txt` file is a text file that contains the list of all lexical units of the text. The first line of this file indicates the number of units found in the file. Units are separated by a newline. Whenever a sequence is found in the text with capitalization variants, each variant is encoded as a distinct unit.

NOTE: Newlines that might be in the `.snt` file are encoded like spaces. Therefore there is no unit encoding the newline.

14.4.5 The `tok_by_alph.txt` and `tok_by_freq.txt` files

These two files are text files that contain the list of lexical units sorted alphabetically or by frequency.

In the `tok_by_alph.txt` file, each line is composed by a unit, followed by a tab and the number of occurrences of the unit within the text.

The lines of the `tok_by_freq.txt` file are formed after the same principle, but the number of occurrences is placed after the tab and the unit.

14.4.6 The `enter.pos` file

This file is a binary file containing the list of positions of the newline symbol in the `.snt` file. Each position is the index in the `text.cod` file where a newline has been replaced by a space. These positions are integers that are encoded in 4 bytes.

14.5 Text Automaton

14.5.1 The `text.tfst` file

The `text.tfst` file represents the text automaton. It is a text file that starts with a ten digit line indicating the number of sentence automata it contains. Then, for each sentence automaton, you have the following header lines:

- `$XXX¶`: `XXX` = number of the sentence
- `foo foo foo...¶`: text of the sentence
- `a/b c/d e/f g/h...¶`: for each token of the sentence, we have a pair `x/y`: `x` is the token index in file `tokens.txt`, `y` is the length of the token in characters
- `X_Y¶`: `X` is the offset of the first token of the sentence, in tokens from the beginning of the text; `Y` is the same, but the offset is in characters from the beginning of the text.

Then, all states of the automaton are encoded, one per line. If the state is final, the line starts with `t`. Otherwise, the line starts with `:`. All transitions are written as pairs `x y`, `x` being the number of the tag, `y` being the number of the destination state. Note that, at the opposite of `.fst2` format, lines have not to end with a space. The end of state lines is marked by a line containing `f`.

Finally, all tags are encoded. By convention, the first tag is always the epsilon one:

```
@<E>¶
.¶
```

Other labels have to be either lexical units or entries in the DELAF format in braces. They are encoded as follows:

```
@STD¶
@content¶
@a.b.c-x.y.z¶
.¶
```

content is the tag content. The *a.b.c-x.y.z* information describe the zone in text covered by the tag:

- *a*: start offset in tokens from the beginning of the sentence;
- *b*: start offset in characters from the beginning of the first token of the tag;
- *c*: start offset in logical letters from the first character of the tag. This information is useful for Korean, because a tag can represent a Jamo sequence that occurs inside a Hangul character. Thus, the character offset is not precise enough;
- *x*: end offset in tokens from the beginning of the sentence;
- *y*: end offset in characters from the beginning of the last token of the tag;
- *z*: end offset in logical letters from the last character of the tag. In Korean sentence automata, empty surface forms can occur that correspond to the empty word in the text. In such cases, *z* has special value -1 .

The and of tag definitions is marked by a line containing f .

Example: Here is the file that corresponds to the text *He is drinking orange juice*.

```
0000000001¶
$1¶
He is drinking orange juice. ¶
0/2 1/1 2/2 1/1 3/8 1/1 4/6 1/1 5/5 6/1 1/1¶
0_0¶
: 2 1 1 1¶
: 4 2 3 2¶
: 7 3 6 3 5 3¶
: 10 5 9 4 8 4¶
: 12 5 11 5¶
: 13 6¶
t¶
```

```

14.5.2 The text.tind file

The `text.tind` file is an index file used to jump at correct byte offset in the `text.tfst` file when we want to load a given sentence. It is a binary file that contains $4 \times N$ bytes, where N is the number of sentences. It gives the start offset of each sentence as a 4-byte little-endian sequence.

14.5.3 The cursentence.grf file

The `cursentence.grf` file is generated by Unitex during the display of a sentence automaton. The `Fst2Grf` program constructs a `.grf` file from the `text.fst2` file that represents a sentence automaton.

NOTE: outputs of graph boxes are used to encode offsets, as defined in `.tfst` tags. Offsets are separated with spaces. For instance, here are some lines of the graph representing the first sentence of *Ivanhoe*:

```

"Ivanhoe/0 0 0 0 6 0" 100 200 2 3 4 ¶
"{by,by.PART}/2 0 0 2 1 0" 220 150 2 5 6 ¶
"{by,by.PREP}/2 0 0 2 1 0" 220 50 2 5 6 ¶
"{Sir,sir.N+Hum:s}/4 0 0 4 2 0" 310 200 1 7 ¶

```

14.5.4 The sentenceN.grf file

Whenever the user modifies a sentence automaton, that automaton is saved under the name `sentenceN.grf`, where N represents the number of the sentence. Such a graph contains offsets in graph box outputs (see note in section [14.5.3](#)).

14.5.5 The `cursentence.txt` file

During the extraction of the sentence automaton, the text of the sentence is saved in the file called `cursentence.txt`. That file is used by Unitex to display the text of the sentence under the automaton. That file contains the text of the sentence, followed by a newline.

14.5.6 The `cursentence.tok` file

During the extraction of the sentence automaton, the numbers of the tokens that compose the sentence are stored in a file named `cursentence.tok`. This file contains one line per token, each line being made of 2 integers x y : x is the token number, y is the length of the token in characters.

Here is the content of this file for the first sentence of *Ivanhoe*:

```
0 7¶      Ivanhoe
1 1¶      ⌊
2 2¶      by
1 1¶      ⌊
3 3¶      Sir
1 1¶      ⌊
4 6¶      Walter
1 1¶      ⌊
5 5¶      Scott
1 1¶      ⌊
```

14.5.7 The `tfst_tags_by_freq.txt` and `tfst_tags_by_alph.txt` files

Those files contain all the tags that appear in the text automaton sorted by frequency and alphabetical order.

14.6 Concordances

14.6.1 The `concord.ind` file

The `concord.ind` file is the index of the occurrences found by either `Locate` or `LocateTfst` during the application of a grammar. It is a text file that contains the starting and ending positions of each occurrence, possibly accompanied by a sequence of letters if the construction of the concordance took into account the possible transducer outputs of the grammar. Here is an example of such a file:

```
#M¶
59.0.0 63.3.0 the[ADJ= greater] part¶
```

```

67.0.0 71.4.0 the beautiful hills¶
87.0.0 91.3.0 the pleasant town¶
123.0.0 127.4.0 the noble seats¶
157.0.0 161.5.0 the fabulous Dragon¶
189.0.0 193.3.0 the Civil Wars¶
455.0.0 459.11.0 the feeble interference¶
463.0.0 467.6.0 the English Council¶
566.0.0 570.10.0 the national convulsions¶
590.0.0 594.5.0 the inferior gentry¶
626.0.0 630.11.0 the English constitution¶
696.0.0 700.4.0 the petty kings¶
813.0.0 817.5.0 the certain hazard¶
896.0.0 900.5.0 the great Barons¶
938.0.0 942.3.0 the very edge¶

```

The first line indicates in which transduction mode the concordance has been constructed. The three possible values are:

- #I : transducer outputs have been ignored;
- #M : transducer outputs have been inserted before the corresponding inputs (MERGE mode);
- #R : transducer outputs have replaced the recognized sequences (REPLACE mode)).

Each occurrence is described in one line. The lines start with the start and end positions of the occurrence. These positions corresponds to the offsets defined in `.tfst` tags (see [14.5.1](#)).

If the file has the heading line #I, the end position of each occurrence is immediately followed by a newline. Otherwise, it is followed by a space and a sequence of characters. In REPLACE mode, that sequence corresponds to the output produced for the recognized sequence. In MERGE mode, it represents the recognized sequences into which the outputs have been inserted. In MERGE or REPLACE mode, this sequence is displayed in the concordance. If the outputs have been ignored, the contents of the occurrence is extracted from the text file.

14.6.2 The concord.txt file

The `concord.txt` file is a text file that represents a concordance. Each occurrence is encoded in a line that is composed of three character sequences separated by a tab, representing the left context, the occurrence (possibly modified by transducer outputs) and the right context.

14.6.3 The concord.html file

The `concord.html` file is an HTML file that represents a concordance. This file is encoded in UTF-8.

The title of the page is the number of occurrences it describes. The lines of the concordance are encoded as lines where the occurrences are considered to be hypertext lines. The reference associated to each of these lines has the following form: ``. X and Y represent the start and end position of the occurrence in characters in the file `name_of_text.snt`. Z represents the number of the phrase in which this occurrence appears.

All spaces that are at the left and right edges of lines are encoded by a non breaking space (` ` in HTML), which allows the preservation of the alignment of the occurrences even if one of them has a left context with spaces.

NOTE: If the concordance has been constructed with the `glossanet` parameter, the HTML file has the same structure, except for the links. In these concordances, the occurrences are real links pointing at the web server of the GlossaNet application. For more information on GlossaNet, consult the link on the Unix web site.

Here is an example of a file:

```
<html lang=en>
<head>
  <meta http-equiv="Content-Type" content="text/html;
    charset=UTF-8">
  <title>6 matches</title>
</head>
<body>
<table border="0" cellpadding="0" width="100%"
  style="font-family: 'Arial Unicode MS'; font-size: 12">
<font face="Courier new" size=3>
on, there <a href="116 124 2">extended</a>&nbsp;i&nbsp;<br>
&nbsp;extended <a href="125 127 2">in</a>&nbsp;ancient&nbsp;<br>
&nbsp;Scott {S}<a href="32 34 2">IN</a>&nbsp;THAT PL&nbsp;<br>
STRICT of <a href="61 66 2">merry</a>&nbsp;Engl&nbsp;<br>
S}IN THAT <a href="40 48 2">PLEASANT</a>&nbsp;D&nbsp;<br>
&nbsp;which is <a href="84 91 2">watered</a>&nbsp;by&nbsp;<br>
</font>
</td></table></body>
</html>
```

Figure 14.2 shows the page that corresponds to the file below.

```
</tr>
</table>
</body>
</html>
```

14.7 Text dictionaries

The `Dico` program produces several files that represent text dictionaries.

14.7.1 `dlf` and `dlc`

`dlf` and `dlc` are simple and compound word dictionaries in the DELAF format (see section 3.1.1).

14.7.2 `err`

This file is made of unknown words, one per line.

14.7.3 `tags_err`

This file is made of unknown words, one per line. The difference with the `err` file is that in this one do not appear simple words that have been matched in the `tags.ind` file.

14.7.4 `tags.ind`

This file has the same format than a `concord.ind` one obtained in MERGE or REPLACE mode, but its header is `#T`. Note that the outputs DO NOT BEGIN with a slash.

14.8 Dictionaries

The compression of the DELAF dictionaries by the `Compress` program produces two files: a `.bin` file that represents the minimal automaton of the inflected forms of the dictionaries, and a `.inf` file that contains the compressed forms required for the construction of the dictionaries from the inflected forms. This section describes the format of these two file types, as well as the format of the `CHECK_DIC.TXT` file, which contains the result of the verification of a dictionary.

14.8.1 The .bin files

A `.bin` file is a binary file that represents an automaton. The first 4 bytes of the file represent an integer that indicates the size of the file in bytes. The states of the automaton are encoded in the following way:

- the first two bytes indicate if the state is final as well as the number of its outgoing transitions. The highest bit is 0 if the state is final, 1 if not. The other 15 bits encode the number of transitions.

Example: a non-final state with 17 transitions is encoded by the hexadecimal sequence 8011

- if the state is final, the three following bytes encode the index in the `.inf` file of the compressed form to be used to reconstruct the dictionary lines for this inflected form.

Example: if the state refers to the compressed form with index 25133, the corresponding hexadecimal sequence is 00622D

- each leaving transition is then encoded in 5 bytes. The first 2 bytes encode the character that labels the transition, and the three following encode the byte position of the result state in the `.bin` file. The transitions of a state are encoded next to each other.

Example: a transition that is labeled with the A letter and goes to the state of which the description starts at byte 50106, is represented by the hexadecimal sequence 004100C3BA.

By convention, the first state of the automaton is the initial state.

14.8.2 The .inf files

A `.inf` file is a text file that describes the compressed files that are associated to a `.bin` file. Here an example of a `.inf` file:

```
0000000006¶
_10\0\0\7.N¶
.PREP¶
_3.PREP¶
.PREP,_3.PREP¶
1-1.N+Hum:mp¶
3er 1.N+AN+Hum:fs¶
```

The first line of the file indicates the number of compressed forms that it contains. Each line can contain one or more compressed forms. If there are multiple forms, they are separated by commas. Each compressed form is made up of a sequence required to reconstruct a canonical knowing an inflected form, followed by a sequence of grammatical, semantic and inflection codes that are associated to the entry.

The mode of compression of the canonical form varies in function of the inflected form. If the two forms are identical, the compressed form contains only the grammatical, semantic and inflectional information as in:

```
.N+Hum:ms
```

If the forms are different, the compression program cuts up the two forms in units. These units can be a space, a hyphen, or a sequence of characters that contains neither a space nor a hyphen. This way of cutting up units allows the program to efficiently take into account the inflected forms of the compound words.

If the inflected and the canonical form do not have the same number of units, the program encodes the canonical form by the number of characters to be removed from the inflected form followed by the characters to append. For instance, the line below is a line in the initial dictionary:

```
James Bond,007.N
```

Since the sequence `James Bond` contains three units and `007` only one, the canonical form is encoded with `_10\0\0\7`. The `_` character indicates that the two forms do not have the same number of units. The following number (here 10) indicates the number of characters to be removed. The sequence `\0\0\7` indicates that the sequence `007` should be appended. The digits are preceded by the `\` character so they will not be confused with the number of characters to be removed.

Whenever the two forms have the same number of units, the units are compressed two by two. Each pair consists of a unit the inflected form and the corresponding unit in the canonical form. If each of the two units is a space or a hyphen, the compressed form of the unit is the unit itself, as in the following line:

```
0-1.N:p
```

which is the output for `battle-axes,battle-axe.N:p`

This maintains a certain readability of the `.inf` file when the dictionary contains compound words.

Whenever one or both of the units in a pair is neither a space nor a hyphen, the compressed form is composed of the number of characters to be removed followed by the sequence of characters to be appended. Thus, the dictionary line:

`première partie, premier parti.N+AN+Hum:fs`

is encoded by the line:

```
3er 1.N+AN+Hum:fs
```

The `3er` code indicates that 3 characters are to be removed from the sequence `première` and the characters `er` are to be appended to obtain `premier`. The `1` indicates that only one character needs to be removed from `partie` to obtain `parti`. The number `0` is used whenever it needs to be indicated that no letter should be removed.

14.8.3 Dictionary information file

In the "Apply lexical resources" frame, it is possible for some dictionaries to get some information with a right click. Such information is attached to a `biniou.bin` or `biniou.fst2` dictionary by the mean of a raw text file named `biniou.txt`, located in the same directory.

14.8.4 The CHECK_DIC.TXT file

This file is produced by the dictionary verification program `CheckDic`. It is a text file that contains information about the analysed dictionary and has four parts.

The first part is the possibly empty list of all syntax errors found in the dictionary: absence of the inflected or the canonical form, the grammatical code, empty lines, etc. Each error is described by the number of the line, a message describing the error, and the contents of the line. Here is an example of a message:

```
Line 12451: unexpected end of line
garden,N:s
```

The second and third parts display the list of grammatical codes and/or semantic and inflectional codes respectively. In order to prevent coding errors, the program reports encodings that contain spaces, tabs, or non-ASCII characters. For instance, if a Greek dictionary contains the `ADV` code where the Greek `Α` character is used instead of the Latin `A` character, the program reports the following warning:

```
ADV warning: 1 suspect char (1 non ASCII char): (0391 D V)
```

Non-ASCII characters are indicated by their hexadecimal character number. In the example below, the code `0391` represents Greek `Α`. Spaces are indicated by the `SPACE` sequence:

```
Km s warning: 1 suspect char (1 space): (K m SPACE s)
```

When the following dictionary is checked:

```
1,2 et 3!,.INTJ
abracadabra,INTJ
supercalifragilisticexpialidocious,.INTJ
damned,. INTJ
Paul,.N+Hum+Hum
eat,.V:W:P1s:Ps:P1p:P2p:P3p
```

the following CHECK_DIC.TXT file is obtained:

```
Line 1: unprotected comma in lemma
1,2 et 3!,.INTJ
Line 2: unexpected end of line
abracadabra,INTJ
Line 5: duplicate semantic code
Paul,.N+Hum+Hum
Line 6: an inflectional code is a subset of another
eat,.V:W:P1s:Ps:P1p:P2p:P3p
-----
----- Stats -----
-----
File: D:\My Unitex\English\Dela\axe.dic

INTJ¶
  INTJ warning: 1 suspect char (1 space): (SPACE I N T J)¶
-----¶
----      0 inflectional code used in dictionary  ----¶
-----¶

```

Note that the inflectional codes of `eat` are not reported, since an error occurred in this line.

14.9 ELAG files

14.9.1 tagset.def file

See section [7.3.6](#), page [177](#).

14.9.2 .lst files

.LST FILES ARE NOT UNICODE FILES.

A `.lst` file contains a list of `.grf` file names. If a file's path is not absolute, it is relative to the location of the `elag.lst` file. Here is the `elag.lst` file used for French:

```

PPVs/PpvIL.grf¶
PPVs/PpvLE.grf¶
PPVs/PpvLUI.grf¶
PPVs/PpvPR.grf¶
PPVs/PpvSeq.grf¶
PPVs/SE.grf¶
PPVs/postpos.grf¶

```

14.9.3 .elg files

`.elg` files contain compiled ELAG rules. These files are in the `.fst2` format.

14.9.4 .rul files

.RUL FILES ARE NOT UNICODE FILES.

A .rul file contains the different .elg files that compose an ELAG rule set. It contains one part per .elg file. Each part lists the ELAG grammars that correspond to a given .elg file. .elg file names are surrounded with angles brackets. The lines that start with a tabulation are considered as comments by the Elag program. Here is the elag.rul file used for French:

```

    PPVs/PpvIL.elg¶
    PPVs/PpvLE.elg¶
    PPVs/PpvLUI.elg¶
<elag.rul-0.elg>¶
    PPVs/PpvPR.elg¶
    PPVs/PpvSeq.elg¶
    PPVs/SE.elg¶
    PPVs/postpos.elg¶
<elag.rul-1.elg>¶

```

14.10 Tagger files

This section presents files produced and used by TrainingTagger and Tagger programs.

14.10.1 The corpus.txt file

This file is used by the TrainingTagger program in order to compute statistics for the Tagger program. It contains sentences where each word is represented in a separate line. Each line representing a word is composed of a word, simple or compound, followed by a slash and the tag of the word. This tag is composed of a grammatical code, sometimes followed by a '+' and syntactic or semantic codes. Inflectional codes are specified after a ':' . If the word is a compound, simple words contained in it must be separated by a '_' . Here is an example of a corpus.txt file :

```

The/DET+Ddef:s¶
GATT/N:s¶
had/V:I3s¶
formerly/ADV¶
a/DET+Dind:s¶
political/A¶
assessment/N:s¶
of/PREP¶
the/DET+Ddef:s¶

```

```

behavior/N:s
of/PREP
foreign_countries/N:p
./PONCT

She/PRO+Nomin:3fs
closed/V:I3s
easily/ADV
her/DET+Poss3fs:p
eyes/N:p
when/CONJ
some/DET+Dadj:p
infractions/N:p
might/V:I3p
appear/V:W
justified/V:K
against/PREP
higher/A
interests/N:p
./PONCT

```

NOTE: Sentences must be delimited by empty lines.

The `.txt` file format can also be used (see section 14.4.1). Each word of the text must be represented by a valid lexical label (`{aujourd'hui, .ADV}`) and sentences are delimited by `{S}`. Here is the previous example in the `.txt` file format :

```

{The, .DET+Ddef:s} {GATT, .N:s} {had, .V:I3s} {formerly, .ADV}
{a, .DET+Dind:s} {political, .A} {assessment, .N:s} {of, .PREP}
{the, .DET+Ddef:s} {behavior, .N:s} {of, .PREP} {foreign countries, .N:p}
{., .PONCT} {S} {She, .PRO+Nomin:3fs} {closed, .V:I3s} {easily, .ADV}
{her, .DET+Poss3fs:p} {eyes, .N:p} {when, .CONJ} {some, .DET+Dadj:p}
{infraction, .N:p} {might, .V:I3p} {appear, .V:W} {justified, .V:K}
{against, .PREP} {higher, .A} {interests, .N:p} {., .PONCT} {S}

```

14.10.2 The tagger data file

The `TrainingTagger` program generates two data files (by default) used by the `Tagger` program in order to compute a second-order hidden Markov model. These files contain unigram, bigram and trigram tuples extracted from the `tagged corpus.txt` file. Tuples are composed of either a sequence of 2 or 3 tags (to compute transition probability) or a word preceded by 0 or 1 tag (to compute emit probability). Units in a tuple must be separated by a tabulation. These tuples are followed by the sequence

of delimiters "," and then an integer representing the number of occurrences of this tuple in the corpus file.

Filenames are suffixed by "cat" or "morph". In the first one, tuples are composed of tags formed of grammatical, syntactic and semantic codes. In the second one, tuples consist in tags formed of grammatical, syntactic and semantic codes and sometimes followed by a ':' and inflectional codes. Here is an example of a data file with "cat" tags :

```

the, .9630¶
those, .236¶
eyes, .32¶
DET+Ddef the, .9630¶
DET+Ddem those, .140¶
PRO+Pdem those, .96¶
N eyes, .32¶
DET N, .62541¶
PREP DET N, .25837¶
¶

```

Here is an example of a data file with "morph" tags :

```

the, .9630¶
those, .236¶
eyes, .32¶
DET+Ddef:s the, .4437¶
DET+Ddef:p the, .5193¶
DET+Ddem:p those, .140¶
PRO+Pdem:p those, .96¶
N:p eyes, .32¶
DET:s N:s, .18489¶
PREP DET:s N:s, .6977¶
¶

```

A special line is added to data files in order to identify whether the file contains "cat" or "morph" tags. This line contains CODE FEATURES followed by either the integer 0 for "cat" tags or 1 for "morph" tags.

NOTE: At the final stage, TrainingTagger compresses these two data files into the ".bin" format.

14.11 Configuration files

14.11.1 The Config file

Whenever the user modifies his preferences for a given languages, these modifications are saved in a text file named 'Config' which can be found in the directory of the current language. The file has the following syntax (the order of lines can vary):

```
#Unitex configuration file of 'paumier' for 'English'
#Fri Oct 10 15:18:06 CEST 2008
TEXT\ FONT\ NAME=Courier New
TEXT\ FONT\ STYLE=0
TEXT\ FONT\ SIZE=10
CONCORDANCE\ FONT\ NAME=Courier new
CONCORDANCE\ FONT\ HTML\ SIZE=12
INPUT\ FONT\ NAME=Times New Roman
INPUT\ FONT\ STYLE=0
INPUT\ FONT\ SIZE=10
OUTPUT\ FONT\ NAME=Arial Unicode MS
OUTPUT\ FONT\ STYLE=1
OUTPUT\ FONT\ SIZE=12
DATE=true
FILE\ NAME=true
PATH\ NAME=false
FRAME=true
RIGHT\ TO\ LEFT=false
BACKGROUND\ COLOR=-1
FOREGROUND\ COLOR=-16777216
AUXILIARY\ NODES\ COLOR=-3289651
COMMENT\ NODES\ COLOR=-65536
SELECTED\ NODES\ COLOR=-16776961
PACKAGE\ NODES\ COLOR=-2302976
CONTEXT\ NODES\ COLOR=-16711936
CHAR\ BY\ CHAR=false
ANTIALIASING=false
HTML\ VIEWER=
MAX\ TEXT\ FILE\ SIZE=2097152
ICON\ BAR\ POSITION=West
PACKAGE\ PATH=D:\repository
MORPHOLOGICAL\ DICTIONARY=D:\MyUnitex\English\Dela\zz.bin
MORPHOLOGICAL\ NODES\ COLOR=-3911728
MORPHOLOGICAL\ USE\ OF\ SPACE=false
```

The first two lines are comment lines. The following three lines indicate the name, the style and the size of the font used to display texts, dictionaries, lexical units, sentences in text automata, etc.

The `CONCORDANCE FONT NAME` and `CONCORDANCE FONT HTML SIZE` parameters define the name, the size and the font to be used when displaying concordances in HTML. The size of the font has a value between 1 and 7.

The `INPUT FONT . . .` and `OUTPUT FONT . . .` parameters define the name, the style and the size of the fonts used for displaying the paths and the transducer outputs of the graphs.

The following 10 parameters correspond to the parameters given in the headings of the graphs. Table 14.5 describes the correspondances.

Parameters in the Config file	Parameters in the .grf file
DATE	DDATE
FILE NAME	DFILE
PATH NAME	DDIR
FRAME	DFRAME
RIGHT TO LEFT	DRIG
BACKGROUND COLOR	BCOLOR
FOREGROUND COLOR	FCOLOR
AUXILIARY NODES COLOR	ACOLOR
COMMENT NODES COLOR	SCOLOR
SELECTED NODES COLOR	CCOLOR

Table 14.5: Meaning of the parameters

The `PACKAGE NODES` parameter defines the color to be used for displaying calls to subgraphs located in the repository.

The `CONTEXT NODES` parameter defines the color to be used for displaying boxes that correspond to context bounds.

The `CONTEXT NODES` indicates if the current language must be tokenized character by character or not.

The `ANTIALIASING` parameter indicates whether graphs as well as sentence automata are displayed by default with the antialiasing effect.

The `HTML VIEWER` parameter indicates the name of the navigator to be used for displaying concordances. If no navigator name is defined, concordances are displayed in a Unitex window.

The `MAX TEXT FILE SIZE` parameter is deprecated.

The `ICON BAR POSITION` parameter indicates the default position of icon bars in graph frames.

The `PACKAGE PATH` parameter specifies the location of the repository.

The `MORPHOLOGICAL DICTIONARY` parameter specifies the list of morphological-mode dictionaries, separated with semi-colons.

The `MORPHOLOGICAL NODES COLOR` parameter specifies the color to use to render the `$<` and `$>` tags.

The `MORPHOLOGICAL USE OF SPACE` parameter indicates if the `Locate` program is allowed to start matching on spaces. Default is false.

14.11.2 The `system_dic.def` file

The `system_dic.def` file is a text file that describes the list of system dictionaries that are applied by default. This file can be found in the directory of the current language. Each line corresponds to a name of a `.bin` file. The system dictionaries are in the `Unitex` system directory, and within that directory, in the `(current language)/Dela` sub-directory. Here is an example of this file:

```
delacf.bin¶
delaf.bin¶
```

14.11.3 The `user_dic.def` file

The `user_dic.def` file is a text file that describes the list of dictionaries the user has defined to be applied by default. This file is in the directory of the current language and has the same format as the `system_dic.def` file. The dictionaries need to be in the `(current language)/Dela` sub-directory of the user's working directory.

14.11.4 The `(user login).cfg` and `.unitex.cfg` files

Under Linux and Mac OS, your working directory is expected to be called `unitex` and to be in your root directory (`$HOME`). If you want to change this default location, a `.unitex.cfg` file is created in your home directory, and it contains the path to your working directory. This file is a UTF8 one. If `.unitex.cfg` does not contain a valid Linux path to an existing directory, it is ignored.¹

¹This allows you to launch Unitex sometimes under Linux, sometimes under Windows, on shared files: the Windows path to your working directory is contained in `.unitex.cfg`, and Unitex ignores it when launched under Linux.

Under Windows, it is not always possible to associate a directory to a user by default. To compensate for that, Unitex creates for each user a `.cfg` file that contains the path to his/her working directory. This file is saved under the name `(user login).cfg` in the `Users` sub-directory of the Unitex system directory. If the user does not have permission to write into this directory, Unitex saves a file named `.unitex.cfg` in the Windows user profile directory:

- in `Documents and Settings\ (user login)` if under Windows XP
- in `Users\ (user login)` if under Windows Vista or later.

WARNING: THIS FILE IS NOT IN UNICODE

WARNING (2): THE PATH OF THE PERSONAL WORKING DIRECTORY IS NOT FOLLOWED BY A NEWLINE.

14.12 CasSys files

14.12.1 CasSys configuration files `csc`

To memorize the list of transducer of a CasSys cascade, we use a text file (`csc` file) in which each line contains the path to a transducer followed by the output policy (merge/replace) to be applied to this transducer. The generic format of a line of `csc` file is : `Name_and_path_of_transducer Merge` Here is an example of cascade file `csc`:

```
"C:\apps\my_unitex\French\Graphs\grf1.fst2" Merge
"C:\apps\my_unitex\French\Graphs\grf2.fst2" Replace
```

14.13 Various other files

For each text, Unitex creates multiple files that contain information that are designed to be displayed in the graphical interface. This section describes these files and some others.

14.13.1 The `dlf.n`, `dlc.n`, `err.n` et `tags_err.n` files

These files are text files that are stored in the text directory. They contain the number of lines of the `dlf`, `dlc`, `err` and `tags_err` files respectively. These numbers are followed by a newline.

14.13.2 The `stat_dic.n` file

This file is a text file in the directory of the text. It has three lines that contain the number of lines of the `dlf`, `dlc` and `err` files.

14.13.3 The stats.n file

This file is in the text directory and contains a line with the following form:

```
3949 sentence delimiters, 169394 (9428 diff) tokens, 73788 (9399)
simple forms, 438 (10) digits¶
```

The numbers indicated are interpreted in the following way:

- `sentence delimiters`: number of sentence delimiters (`{S}`);
- `tokens`: total number of lexical units in the text. The number preceding `diff` indicates the number of different units;
- `simple forms`: the total number of lexical units in the text that are composed of letters. The number in parentheses represents the number of different lexical units that are composed of letters;
- `digits`: the total number of digits used in the text. The number in parentheses indicates the number of different digits used (10 at most).

14.13.4 The concord.n file

The `concord.n` file is a text file in the directory of the text. It contains information on the latest search of the text and looks like the following:

```
6 matches¶
6 recognized units¶
(0.004% of the text is covered)¶
```

The first line gives the number of found occurrences, and the second the name of units covered by these occurrences. The third line indicates the ratio between the covered units and the total number of units in the text.

14.13.5 The concord_tfst.n file

The `concord_tfst.n` file is a text file in the directory of the text. It contains information on the latest search on the text automaton and looks like the following:

```
23 matches (45 outputs)¶
```

14.13.6 Normalization rule file

This file is used by the `Normalization` and `XMLizer` programs. It represents replacement rules. Each line stands for a rule, according to the following format (`␣` stands for the tabulation character):

input sequence \mapsto output sequence

If you want to use the tabulation or the new line, you must protect them with a backslash like this:

```
123\  

 $\mapsto$  ONE_TWO_THREE_NEW_LINE
```

14.13.7 Forbidden word file

The `PolyLex` programs requires a forbidden word file for Dutch and Norwegian. This raw text file is supposed to be named `ForbiddenWords.txt`. It must be in the user's `Dela` directory corresponding to the language to work on. Each line is supposed to contain one forbidden word.

14.13.8 Log file

The `UnitexToolLogger` programs, when a `unitex_logging_parameters.txt` file is found with a path (to store logfile) creates `.ulp` file with a log of the running Unitex tool selected. It creates a `unitex_logging_parameters_count.txt` file which contain only the number of latest log file created.

Log file (with `.ulp` extension) are uncompressed zipfile, compatible with `unzip` and all standard `unzip` tools. It contain these files:

- `test_info/command_line.txt`: a list of parameter of the command line used to run the tool. There is one parameter on each line. The first line contain the return value, the second line the number of parameters;
- `test_info/command_line_synth.txt`: a simple line with a summary of the command line used to run the tool;
- `test_info/list_file_in.txt`: a list of file read by the tool. The first column is file size, second column is `crc32`, third is filename;
- `test_info/list_file_out.txt`: a list of file created by the tool. The first column is file size, second column is `crc32`, third is filename;
- `test_info/std_out.txt`: content of standard console output;
- `test_info/std_err.txt`: content of error console output;
- `src/xxx`: a copy of file read by the tool (needed to run the log again);
- `dest/xxx`: a copy of file created by the tool.

If the second line of `unitex_logging_parameters.txt` contains 0, these file are not recorded; if this line contains 1, they are recorded;

14.13.9 Arabic typographic rules: `arabic_typo_rules.txt`

For Arabic, dictionary lookups can be parameterized with a file that describes whether some typographic variations are allowed or not. This file is made of lines like the following:

```
fatha omission=YES
```

where `fatha omission` is the name of the rule. For a complete description of all the available rules, you have to consult the `Arabic.h` file in the program sources.

14.13.10 Offsets file of difference

Offsets file of difference are write by `Unxmlize(13.50)`, read by `Tokenize(13.43)`, read and write by `DumpOffsets(13.13)`, `Normalize(13.29)`, `Fst2Txt(13.21)`, `Tokenize(13.43)`, `Concord(13.9)` and `GrfTest`. These files contain line with 4 integers A B C D. Each

line mean there is a text modification: The text at position [A;B] before applying modification is replaced by text at position [C;D] after computing, A, B, C and D are offsets (in characters) into text files.

By example, if we run `Normalize` on text `texte "Hello world"` (with two space between the 2 words), the offsets file is:

```
5 7 5 6
```

This mean we replace two characters (the two spaces) by a new string of one characters.

Each programs which modify text build a new offsets file. If we provide a previous offsets file (build by previous program which made previous modification), offsets file will be combined.

Appendix A - GNU Lesser General Public License

This license can also be found in [\[36\]](#).

GNU LESSER GENERAL PUBLIC LICENSE Version 2.1, February 1999

Copyright (C) 1991, 1999 Free Software Foundation, Inc. 59 Temple Place, Suite 330, Boston, MA 02111-1307 USA Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

[This is the first released version of the Lesser GPL. It also counts as the successor of the GNU Library Public License, version 2, hence the version number 2.1.]

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public Licenses are intended to guarantee your freedom to share and change free software—to make sure the software is free for all its users.

This license, the Lesser General Public License, applies to some specially designated software packages—typically libraries—of the Free Software Foundation and other authors who decide to use it. You can use it too, but we suggest you first think carefully about whether this license or the ordinary General Public License is the better strategy to use in any particular case, based on the explanations below.

When we speak of free software, we are referring to freedom of use, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish); that you receive source code or can get it if you want it; that you can change the software and use pieces of it in new free programs; and that you are informed that you can do these things.

To protect your rights, we need to make restrictions that forbid distributors to deny you these rights or to ask you to surrender these rights. These restrictions

translate to certain responsibilities for you if you distribute copies of the library or if you modify it.

For example, if you distribute copies of the library, whether gratis or for a fee, you must give the recipients all the rights that we gave you. You must make sure that they, too, receive or can get the source code. If you link other code with the library, you must provide complete object files to the recipients, so that they can relink them with the library after making changes to the library and recompiling it. And you must show them these terms so they know their rights.

We protect your rights with a two-step method: (1) we copyright the library, and (2) we offer you this license, which gives you legal permission to copy, distribute and/or modify the library.

To protect each distributor, we want to make it very clear that there is no warranty for the free library. Also, if the library is modified by someone else and passed on, the recipients should know that what they have is not the original version, so that the original author's reputation will not be affected by problems that might be introduced by others.

Finally, software patents pose a constant threat to the existence of any free program. We wish to make sure that a company cannot effectively restrict the users of a free program by obtaining a restrictive license from a patent holder. Therefore, we insist that any patent license obtained for a version of the library must be consistent with the full freedom of use specified in this license.

Most GNU software, including some libraries, is covered by the ordinary GNU General Public License. This license, the GNU Lesser General Public License, applies to certain designated libraries, and is quite different from the ordinary General Public License. We use this license for certain libraries in order to permit linking those libraries into non-free programs.

When a program is linked with a library, whether statically or using a shared library, the combination of the two is legally speaking a combined work, a derivative of the original library. The ordinary General Public License therefore permits such linking only if the entire combination fits its criteria of freedom. The Lesser General Public License permits more lax criteria for linking other code with the library.

We call this license the "Lesser" General Public License because it does Less to protect the user's freedom than the ordinary General Public License. It also provides other free software developers Less of an advantage over competing non-free programs. These disadvantages are the reason we use the ordinary General Public License for many libraries. However, the Lesser license provides advantages in certain special circumstances.

For example, on rare occasions, there may be a special need to encourage the widest possible use of a certain library, so that it becomes a de-facto standard. To achieve this, non-free programs must be allowed to use the library. A more frequent case is that a free library does the same job as widely used non-free libraries. In this case, there is little to gain by limiting the free library to free software only, so we use the Lesser General Public License.

In other cases, permission to use a particular library in non-free programs enables a greater number of people to use a large body of free software. For example, permission to use the GNU C Library in non-free programs enables many more people to use the whole GNU operating system, as well as its variant, the GNU/Linux operating system.

Although the Lesser General Public License is Less protective of the users' freedom, it does ensure that the user of a program that is linked with the Library has the freedom and the wherewithal to run that program using a modified version of the Library.

The precise terms and conditions for copying, distribution and modification follow. Pay close attention to the difference between a "work based on the library" and a "work that uses the library". The former contains code derived from the library, whereas the latter must be combined with the library in order to run.

GNU LESSER GENERAL PUBLIC LICENSE TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License Agreement applies to any software library or other program which contains a notice placed by the copyright holder or other authorized party saying it may be distributed under the terms of this Lesser General Public License (also called "this License"). Each licensee is addressed as "you".

A "library" means a collection of software functions and/or data prepared so as to be conveniently linked with application programs (which use some of those functions and data) to form executables.

The "Library", below, refers to any such software library or work which has been distributed under these terms. A "work based on the Library" means either the Library or any derivative work under copyright law: that is to say, a work containing the Library or a portion of it, either verbatim or with modifications and/or translated straightforwardly into another language. (Hereinafter, translation is included without limitation in the term "modification".)

"Source code" for a work means the preferred form of the work for making modifications to it. For a library, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the library.

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running a program using the Library is not restricted, and output from such a program is covered only if its contents constitute a work based on the Library (independent of the use of the Library in a tool for writing it). Whether that is true depends on what the Library does and what the program that uses the Library does.

1. You may copy and distribute verbatim copies of the Library's complete source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and distribute a copy of this License along with the Library.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Library or any portion of it, thus forming a work based on the Library, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

- a) The modified work must itself be a software library.
- b) You must cause the files modified to carry prominent notices stating that you changed the files and the date of any change.
- c) You must cause the whole of the work to be licensed at no charge to all third parties under the terms of this License.
- d) If a facility in the modified Library refers to a function or a table of data to be supplied by an application program that uses the facility, other than as an argument passed when the facility is invoked, then you must make a good faith effort to ensure that, in the event an application does not supply such function or table, the facility still operates, and performs whatever part of its purpose remains meaningful.

(For example, a function in a library to compute square roots has a purpose that is entirely well-defined independent of the application. Therefore, Subsection 2d requires that any application-supplied function or table used by this function must be optional: if the application does not supply it, the square root function must still compute square roots.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Library, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Library, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Library.

In addition, mere aggregation of another work not based on the Library with the Library (or with a work based on the Library) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may opt to apply the terms of the ordinary GNU General Public License instead of this License to a given copy of the Library. To do this, you must alter all the notices that refer to this License, so that they refer to the ordinary GNU General

Public License, version 2, instead of to this License. (If a newer version than version 2 of the ordinary GNU General Public License has appeared, then you can specify that version instead if you wish.) Do not make any other change in these notices.

Once this change is made in a given copy, it is irreversible for that copy, so the ordinary GNU General Public License applies to all subsequent copies and derivative works made from that copy.

This option is useful when you wish to copy part of the code of the Library into a program that is not a library.

4. You may copy and distribute the Library (or a portion or derivative of it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange.

If distribution of object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place satisfies the requirement to distribute the source code, even though third parties are not compelled to copy the source along with the object code.

5. A program that contains no derivative of any portion of the Library, but is designed to work with the Library by being compiled or linked with it, is called a "work that uses the Library". Such a work, in isolation, is not a derivative work of the Library, and therefore falls outside the scope of this License.

However, linking a "work that uses the Library" with the Library creates an executable that is a derivative of the Library (because it contains portions of the Library), rather than a "work that uses the library". The executable is therefore covered by this License. Section 6 states terms for distribution of such executables.

When a "work that uses the Library" uses material from a header file that is part of the Library, the object code for the work may be a derivative work of the Library even though the source code is not. Whether this is true is especially significant if the work can be linked without the Library, or if the work is itself a library. The threshold for this to be true is not precisely defined by law.

If such an object file uses only numerical parameters, data structure layouts and accessors, and small macros and small inline functions (ten lines or less in length), then the use of the object file is unrestricted, regardless of whether it is legally a derivative work. (Executables containing this object code plus portions of the Library will still fall under Section 6.)

Otherwise, if the work is a derivative of the Library, you may distribute the object code for the work under the terms of Section 6. Any executables containing that work also fall under Section 6, whether or not they are linked directly with the Library itself.

6. As an exception to the Sections above, you may also combine or link a "work that uses the Library" with the Library to produce a work containing portions of the Library, and distribute that work under terms of your choice, provided that the terms permit modification of the work for the customer's own use and reverse

engineering for debugging such modifications.

You must give prominent notice with each copy of the work that the Library is used in it and that the Library and its use are covered by this License. You must supply a copy of this License. If the work during execution displays copyright notices, you must include the copyright notice for the Library among them, as well as a reference directing the user to the copy of this License. Also, you must do one of these things:

a) Accompany the work with the complete corresponding machine-readable source code for the Library including whatever changes were used in the work (which must be distributed under Sections 1 and 2 above); and, if the work is an executable linked with the Library, with the complete machine-readable "work that uses the Library", as object code and/or source code, so that the user can modify the Library and then relink to produce a modified executable containing the modified Library. (It is understood that the user who changes the contents of definitions files in the Library will not necessarily be able to recompile the application to use the modified definitions.)

b) Use a suitable shared library mechanism for linking with the Library. A suitable mechanism is one that (1) uses at run time a copy of the library already present on the user's computer system, rather than copying library functions into the executable, and (2) will operate properly with a modified version of the library, if the user installs one, as long as the modified version is interface-compatible with the version that the work was made with.

c) Accompany the work with a written offer, valid for at least three years, to give the same user the materials specified in Subsection 6a, above, for a charge no more than the cost of performing this distribution.

d) If distribution of the work is made by offering access to copy from a designated place, offer equivalent access to copy the above specified materials from the same place.

e) Verify that the user has already received a copy of these materials or that you have already sent this user a copy.

For an executable, the required form of the "work that uses the Library" must include any data and utility programs needed for reproducing the executable from it. However, as a special exception, the materials to be distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

It may happen that this requirement contradicts the license restrictions of other proprietary libraries that do not normally accompany the operating system. Such a contradiction means you cannot use both them and the Library together in an executable that you distribute.

7. You may place library facilities that are a work based on the Library side-by-side in a single library together with other library facilities not covered by this License, and distribute such a combined library, provided that the separate distribu-

tion of the work based on the Library and of the other library facilities is otherwise permitted, and provided that you do these two things:

a) Accompany the combined library with a copy of the same work based on the Library, uncombined with any other library facilities. This must be distributed under the terms of the Sections above.

b) Give prominent notice with the combined library of the fact that part of it is a work based on the Library, and explaining where to find the accompanying uncombined form of the same work.

8. You may not copy, modify, sublicense, link with, or distribute the Library except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense, link with, or distribute the Library is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

9. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Library or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Library (or any work based on the Library), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Library or works based on it.

10. Each time you redistribute the Library (or any work based on the Library), the recipient automatically receives a license from the original licensor to copy, distribute, link with or modify the Library subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties with this License.

11. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Library at all. For example, if a patent license would not permit royalty-free redistribution of the Library by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Library.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply, and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution sys-

tem which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

12. If the distribution and/or use of the Library is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Library under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

13. The Free Software Foundation may publish revised and/or new versions of the Lesser General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Library specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Library does not specify a license version number, you may choose any version ever published by the Free Software Foundation.

14. If you wish to incorporate parts of the Library into other free programs whose distribution conditions are incompatible with these, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

15. BECAUSE THE LIBRARY IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE LIBRARY, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE LIBRARY "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE LIBRARY IS WITH YOU. SHOULD THE LIBRARY PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

16. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE LIBRARY AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE LIBRARY (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE LIBRARY TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Libraries

If you develop a new library, and you want it to be of the greatest possible use to the public, we recommend making it free software that everyone can redistribute and change. You can do so by permitting redistribution under these terms (or, alternatively, under the terms of the ordinary General Public License).

To apply these terms, attach the following notices to the library. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

<one line to give the library's name and a brief idea of what it does.> Copyright (C) <year> <name of author>

This library is free software; you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation; either version 2.1 of the License, or (at your option) any later version.

This library is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this library; if not, write to the Free Software Foundation, Inc., 59 Temple Place, Suite 330, Boston, MA 02111-1307 USA

Also add information on how to contact you by electronic and paper mail.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the library, if necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the library 'Frob' (a library for tweaking knobs) written by James Random Hacker.

<signature of Ty Coon>, 1 April 1990 Ty Coon, President of Vice

That's all there is to it!

Appendix B - 2-clause BSD-style Licenses

B.1. TRE

This is the license, copyright notice, and disclaimer for TRE, a regex matching package (library and tools) with support for approximate matching.

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix at the following address: <http://www.apache.org/licenses/>).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. **Grant of Copyright License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. **Grant of Patent License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. **Redistribution.** You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

1. You must give any other recipients of the Work or Derivative Works a copy of this License; and
2. You must cause any modified files to carry prominent notices stating that You changed the files; and
3. You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
4. If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. **Submission of Contributions.** Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. **Trademarks.** This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. **Disclaimer of Warranty.** Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions)

on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. **Limitation of Liability.** In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. **Accepting Warranty or Additional Liability.** While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

Appendix D - LibYAML's MIT License

This is the license, copyright notice, and disclaimer for LibYAML, an Open Source YAML 1.1 parser and emitter written in C.

Copyright (c) 2006 Kirill Simonov

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. Appendix E - SVNKit's TMatе Open Source License

This is the license, copyright notice, and disclaimer for SVNKit, an Open Source pure Java Subversion library by TMatе Software.

This license applies to all portions of TMatе SVNKit library which are not externally-maintained libraries (e.g. Ganymed SSH library).

All the source code and compiled classes in package `org.tigris.subversion.javahl` except `SvnClient` class are covered by the license in `JAV AHL-LICENSE` file

Copyright © 2004-2009, TMatе Software

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. Redistributions in any form must be accompanied by information on how to obtain complete source code for the software that uses SVNKit and any accompanying software that uses the software that uses SVNKit. The source code must either be included in the distribution or be available for no more than the cost of distribution plus a nominal fee, and must be freely redistributable under reasonable conditions. For an executable file, complete source code means the source code for all modules it contains. It does not include source code for modules or files that typically accompany the major components of the operating system on which the executable file runs.
4. Redistribution in any form without redistributing source code for software that uses SVNKit is possible only when such redistribution is explicitly permitted by TMatе Software. Please, contact TMatе Software at support@svnkit.com to get such permission.

THIS SOFTWARE IS PROVIDED BY TMATE SOFTWARE "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, OR NON-INFRINGEMENT, ARE DISCLAIMED.

IN NO EVENT SHALL TMATE SOFTWARE BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Appendix F - Lesser General Public License For Linguistic Resources

This license was designed by the University of Marne-la-Vallée. It has received the approval of the Free Software Foundation ([1]) and belongs to the List of Open Source Licences (from version 2.1) of the Software Package Data Exchange (SPDX) of the Linux Foundation.

Preamble

The licenses for most data are designed to take away your freedom to share and change it. By contrast, this License is intended to guarantee your freedom to share and change free data—to make sure the data are free for all their users.

This license, the Lesser General Public License for Linguistic Resources, applies to some specially designated linguistic resources – typically lexicons, grammars, thesauri and textual corpora.

TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License Agreement applies to any Linguistic Resource which contains a notice placed by the copyright holder or other authorized party saying it may be distributed under the terms of this Lesser General Public License for Linguistic Resources (also called "this License"). Each licensee is addressed as "you".

A "linguistic resource" means a collection of data about language prepared so as to be used with application programs.

The "Linguistic Resource", below, refers to any such work which has been distributed under these terms. A "work based on the Linguistic Resource" means either the Linguistic Resource or any derivative work under copyright law: that is to say, a work containing the Linguistic Resource or a portion of it, either verbatim or with modifications and/or translated straightforwardly into another language. (Hereinafter, translation is included without limitation in the term "modification".)

"Legible form" for a linguistic resource means the preferred form of the resource for making modifications to it.

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running a program using the Linguistic Resource is not restricted, and output from such a program is covered only if its contents constitute a work based on the Linguistic Resource (independent of the use of the Linguistic Resource in a tool for writing it). Whether that is true depends on what the program that uses the Linguistic Resource does.

1. You may copy and distribute verbatim copies of the Linguistic Resource as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and distribute a copy of this License along with the Linguistic Resource.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Linguistic Resource or any portion of it, thus forming a work based on the Linguistic Resource, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:
 - (a) The modified work must itself be a linguistic resource.
 - (b) You must cause the files modified to carry prominent notices stating that you changed the files and the date of any change.
 - (c) You must cause the whole of the work to be licensed at no charge to all third parties under the terms of this License.

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Linguistic Resource, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Linguistic Resource, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Linguistic Resource.

In addition, mere aggregation of another work not based on the Linguistic Resource with the Linguistic Resource (or with a work based on the Linguistic Resource) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. A program that contains no derivative of any portion of the Linguistic Resource, but is designed to work with the Linguistic Resource (or an encrypted form of the Linguistic Resource) by reading it or being compiled or linked with it, is called a "work that uses the Linguistic Resource". Such a work, in isolation, is not a derivative work of the Linguistic Resource, and therefore falls outside the scope of this License.

However, combining a "work that uses the Linguistic Resource" with the Linguistic Resource (or an encrypted form of the Linguistic Resource) creates a package that is a derivative of the Linguistic Resource (because it contains portions of the Linguistic Resource), rather than a "work that uses the Linguistic Resource". If the package is a derivative of the Linguistic Resource, you may distribute the package under the terms of Section 4. Any works containing that package also fall under Section 4.

4. As an exception to the Sections above, you may also combine a "work that uses the Linguistic Resource" with the Linguistic Resource (or an encrypted form of the Linguistic Resource) to produce a package containing portions of the Linguistic Resource, and distribute that package under terms of your choice, provided that the terms permit modification of the package for the customer's own use and reverse engineering for debugging such modifications.

You must give prominent notice with each copy of the package that the Linguistic Resource is used in it and that the Linguistic Resource and its use are covered by this License. You must supply a copy of this License. If the package during execution displays copyright notices, you must include the copyright notice for the Linguistic Resource among them, as well as a reference directing the user to the copy of this License. Also, you must do one of these things:

- (a) Accompany the package with the complete corresponding machine-readable legible form of the Linguistic Resource including whatever changes were used in the package (which must be distributed under Sections 1 and 2 above); and, if the package contains an encrypted form of the Linguistic Resource, with the complete machine-readable "work that uses the Linguistic Resource", as object code and/or source code, so that the user can modify the Linguistic Resource and then encrypt it to produce a modified package containing the modified Linguistic Resource.
- (b) Use a suitable mechanism for combining with the Linguistic Resource. A suitable mechanism is one that will operate properly with a modified version of the Linguistic Resource, if the user installs one, as long as the mod-

ified version is interface-compatible with the version that the package was made with.

- (c) Accompany the package with a written offer, valid for at least three years, to give the same user the materials specified in Subsection 4a, above, for a charge no more than the cost of performing this distribution.
- (d) If distribution of the package is made by offering access to copy from a designated place, offer equivalent access to copy the above specified materials from the same place.
- (e) Verify that the user has already received a copy of these materials or that you have already sent this user a copy.

If the package includes an encrypted form of the Linguistic Resource, the required form of the "work that uses the Linguistic Resource" must include any data and utility programs needed for reproducing the package from it. However, as a special exception, the materials to be distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

It may happen that this requirement contradicts the license restrictions of proprietary libraries that do not normally accompany the operating system. Such a contradiction means you cannot use both them and the Linguistic Resource together in a package that you distribute.

5. You may not copy, modify, sublicense, link with, or distribute the Linguistic Resource except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense, link with, or distribute the Linguistic Resource is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.
6. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Linguistic Resource or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Linguistic Resource (or any work based on the Linguistic Resource), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Linguistic Resource or works based on it.
7. Each time you redistribute the Linguistic Resource (or any work based on the Linguistic Resource), the recipient automatically receives a license from the original licensor to copy, distribute, link with or modify the Linguistic Resource subject to these terms and conditions. You may not impose any further

restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties with this License.

8. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Linguistic Resource at all. For example, if a patent license would not permit royalty-free redistribution of the Linguistic Resource by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Linguistic Resource.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply, and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free resource distribution system which is implemented by public license practices. Many people have made generous contributions to the wide range of data distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute resources through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

9. If the distribution and/or use of the Linguistic Resource is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Linguistic Resource under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.
10. The Free Software Foundation may publish revised and/or new versions of the Lesser General Public License for Linguistic Resources from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Linguistic Resource specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either

of that version or of any later version published by the Free Software Foundation. If the Linguistic Resource does not specify a license version number, you may choose any version ever published by the Free Software Foundation.

11. If you wish to incorporate parts of the Linguistic Resource into other free programs whose distribution conditions are incompatible with these, write to the author to ask for permission.

NO WARRANTY

12. BECAUSE THE LINGUISTIC RESOURCE IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE LINGUISTIC RESOURCE, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE LINGUISTIC RESOURCE "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE LINGUISTIC RESOURCE IS WITH YOU. SHOULD THE LINGUISTIC RESOURCE PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.
13. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE LINGUISTIC RESOURCE AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE LINGUISTIC RESOURCE (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE LINGUISTIC RESOURCE TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.
